I'm looking for information on the web about transmission line
transformers.
Specifically I want to transform about 150 ohms to about 10 ohms using
a TLT.
Thanks
Mike

The meter is still good. The glitch diodes did their job protecting it.

Source record: 51044

This should not be difficult to do. In order to calculate the shunt resistance you need, you need a few pieces of information:

1) The desired full scale meter current. THis is likely marked on the meter.
2) The meter movement full scale current, without the shunt.
3) The meter movement full scale voltage, without the shunt.

Like I said, #1 is likely what the meter face now reads at full scale. Suppose it is 500 ma.

You can measure #2 and #3. Lets make a guess that this is a 1 ma movement meter. If you have 12v
supply, that would take a series resistor of 12/.001 or a 12K resistor in series with the meter and 12v to get 1 ma.

Take instead a 50K pot, set it half way (very important!) and place it between the meter and the 12v.

12v -> 50K pot -> meter -> ground. Carefully adjust the pot so that the meter reads exactly full scale deflection. If the meter pegs right off the bat, it might be a 50 or 100 ua movement, so drop back and start with a 500K pot set to halfway and repeat. At halfway on the pot, the meter ought not read full scale at first.

Once the meter is reading full scale, place a voltmeter across the meter and measure the voltage drop across the meter. Call it Vm. Also measure the power supply voltage. Call it Vps.

Take things apart and measure the resistance of pot. Call it Rp.

Full scale current of the meter movement (call it Im) is then: (Vps - Vm)/Rp = Im

Call the desired full scale meter reading Id.

Since the meter will need Vm volts to deflect full scale, the total shunt resistance needed is:
Vm/Id = total shunt resistance. Call this Rts. However, the real shunt resistance needs to account for the current through the meter.
Therefore, the real shunt resistance you need is:

Vm/(Id-Im) = desired shunt resistance. Notice that Id is probably large compared to Im, so you could probably ignore it.

Lets do an example. The meter face shows 500 ma at full scale (Id). You use your 12v power supply as a voltage source. You use a 50K pot in series with the meter, and the meter does not peg, but read about half

scale. Carefully adjust the pot to get a full scale reading on the meter. When you get a full scale reading on the meter, You measure your power supply to be 12.8v. Vps = 12.8v. You measure the voltage across the meter as 0.85v, Vm. You take the circuit apart and measure the pot to be 10.5K ohms, Rp.

The meter full scale current is (Vps-Vm)/Rp = (12.8 - 0.85)/10500 = 0.0011 A or 1.1 mA.

The shunt value is: Vm/(Id-Im) = 0.85/(0.5 - 0.0011) = 1.7 ohms.

I built a two-tube Doerle regen SW receiver and can tell absolutely no
difference between using the 30 vs the 01A in that circuit. I've seen
the circuit depicted in articles using either tube.

4752. Re: AEA LA-30 Amp Help!

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-11 04:56:00 UTC
From: Dan Tayloe <dtayloe@home.com>
Message-ID: <3B74BADF.E1354135@home.com>
Source record: 50949

In the following example, the shunt resistor needed was 1.7 ohms.
Suppose that the store down the corner does not have 1.7 ohm resistors,
but instead has 2.2 ohm resistors.

At the desired 0.5A current, you want 0.0011 A through the meter, and
0.4989 A through the 2.2 ohm shunt. Therefore, the voltage drop across
the 2.2 ohm shunt will be 2.2*0.4989 = 1.098v instead of the desired
0.85v.

What we really want is 0.85v across the meter, not 1.098v. Solution:
Add a small resistor in series with the meter as it sits across the 2.2
ohm shunt resistor to get rid of the excess shunt voltage.

This resistor would be: (1.098v - 0.85v)/0.0011A = 225 ohm. A 220 ohm
resistor will be close enough. If you want to be exact, use a 500 ohm
trimpot and set it to the proper value.

A check on the power requirements for the shunt resistor: P = I*I*R =
0.5*0.5*2.2 = 0.55w
Use at least a 1w resistor. You could put two 1 ohm, 1/2w resistors in
series (2 ohm) or two 4.7 ohm in parallel (2.35 ohm) for a shunt and
recalculate the needed meter series resistor.

The main point is that it is not necessary to try to custom wind your
own shunt resistor out of a length of wire. You can find a shunt a
little larger than needed and compensate for the larger than required
shunt voltage by adding additional series meter resistance.

I did the same thing in the mid-1930s. Oof course the
'30 is a lot easier on the 6 volt car battery, especially if the cell
connectors are exposed on top so that you don't have to use a dropping
rheostat (same thing with dry cells). Miki VE7AFN.

What frequency band is the amp for? Be careful of those bakelite SO239
connectors, they can be lossy at higher freqs.

Elaine,

I can't be bothered to go to that website. I have better things to do.

I can't be bothered to learn about your study and online survey.

However, I'll let you into a little secret....
I use the internet, and I am male.

I hope this helps.

However....

I worry about people like you. I feel that you are devoting a lot of
your formative years researching something totally irrelevant to the
real world. I could say "Get a life", but that would be gentlemanly.
Only a male would say this!

Ian.

I was at a show recently and had a chance to check out the radio setup inside on of the police cars. This unit had a device in it that was hooked up to the police radio, and to the car stereo speakers. When the police radio unsquelched, the AM/FM was cut out, and the police radio was heard over the stereo speakers. When the audio disappeared, the music came back.

Any ideas if this is a custom device, or something that is sold somewhere??

Wild guess -- Sears sold WLS (World's Largest Store) brand tubes in the twenties. It was a tie-in to the Chicago radio station they started. I believe the WLS logo was written out in a lightning bolt font. Could the 2976 be a munged up 201A? Or maybe a date code?

You might find more help on the rec.antiques.radio+phono newsgroup.

I may be wrong, and someone please correct me, but these are used in a "reflex" receiver. By use of the transformers, the audio is fed back through the tubes doing the RF amplification, and there is more gain. A search on "reflex receiver" will bring up all kinds of interesting articles.

There was a page I found whose link I have since lost that advocated reversing the order of the tubes for the audio path so as to avoid overload. I will try and find it again.

Well, you could try looking in the mother of all police gadgets: www.galls.com.

But, since you cross-posted to a ham radio homebrewing NG:

This is not rocket science and could be a very simple device that takes a logical high or low from the squelch gate of the radio, switches between the audio source of the broadcast radio, maintains a constant impedance for the public safety radio when it splits it into left and right for the stereo speakers (be careful - some are 4, 8 or 16 ohms; some are odd, like 3.2, etc. "Close" could burn out some of the hybrid IC audio PA modules - likewise, some audio outputs, like on Spectras, are balanced and have a DC bias on the output. NEVER ground it or you will likely damage the audio PA... first the audio PA fuse blows... then this damage could manifest as distortion or latent failure and is not always immediate) and the public safety radio and (hopefully) provides a load at the appropriate impedance for each radio when in the idle mode.

You could make this on a nifty little PC board and house it in a small box.

Good luck.

4764. Invitation to Digital Europe

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-12 17:52:19 UTC
From: digimon36@email.com
Message-ID: <1ec32c97.0108120952.42ee08bf@posting.google.com>
Source record: 50961

Hello,

All 460 Euro-Sat members and new people have been invited to join the
Digital Europe Group,
I cannot subcribe all old members of Euro-Sat directly because we are
a new list.
We are a new beginning list without list activities. It takes a little
time until this mailing list ready for discussions.

JOIN NOW, IT'S EASY:

To subscribe to this group, send an email to:
digital-europe-subscribe@yahoogroups.com
To subscribe a digest, send an email with the subject "subscribe
digest" to:
digimon36@eListas.net
Help: digimon36@email.com

- who started and owns this list
Guenter digimon36@email.com the owner and administrator of Digital
Europe.

- what are the aims of this list
The aim of this list is a legal mailing list which unite the European
digital
satellite television scene in one mailing list. We got in such a
group more
information about digidtal satellite television in Europe.

- what are the topics to be discussed
- digital satellite television
- channels
- feeds
- receivers
- equipment
- installation
- firmware
- DVB 2000

- what is allowed:
- topic discussions

- what is forbidden:
- Insults
- illegal activities - Yahoogroups shut down the list

- Languages of the list
- the mean language for everybody in this mailing list is English!

Regards,

Guenter Moderator, Digital Europe

I still have BNC chassis connectors for (about 300)

25 for $12.40
50 for $21.00
100 for $36.00

and I have some PN2222A's left for (About 300)

50 for $4.50
100 for $8.25
200 for $15.50
500 for $37.00

Let me know if you're interested. All prices are post paid to the USA.

4766. Need info on artificial center tap

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-12 19:16:46 UTC
From: Jim DiMauro <jfd@warwick.net>
Message-ID: <9l6l4qgda1@news.warwick.net>
Source record: 50963

I have a power supply with a damaged xfmr: the center tap seems no longer to be connected internally due to overheating. Otherwise, the HV winding is OK. I have a construction article where the author needed a center-tapped filament winding for his project, but the particulat xfmr he had wasn't center-tapped. He made an artificial center tap by putting a resistor to ground from each side of the winding (in this case he used 33 ohm, 1 watt resistors on a 6.3 volt 8 amp winding). I'd like to do the same for my damaged xfmr, but I don't know how to calculate the value of the resistors. Can anyone out there help?

Thanx.

Wouldn't try that - better to change the configuration of the rectifiers
and work with the single non-tapped winding.

Resistive taps on low-voltage windings were very common "in the old days"
but aren't a very good idea with high-voltage windings. Too much power
wasted, for one thing.

4769. How to? Unsoldering SMT Device (electrolytic caps)

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-12 22:07:29 UTC
From: Joe Leikhim <jleikhim@nettally.com>
Message-ID: <3B76FE20.F2551BD2@nettally.com>
Source record: 50966

I have commercial radio some equipment that uses SMT devices. Some of the small cylindrical 10uf 16 volt electrolytic caps are becoming leaky, losing electrolyte onto the PC board. I would like to remove these and replace with better caps. I suspect that they are glued to the board prior to soldering. I don't have a hot air unit but would like to remove them without tearing up traces due to solder or glue adhering to the PCB. The component density is not too bad, still I dont want to apply heat to other components. Has anyone a good trick to removing these?

If the set uses a filament rheostat, it will have little effect on the
30 due to lower current draw.

Source record: 50971

A quick internet search produced:

1N3492 Diodes Rectifier >5A 100V 25A

Thus it's a garden variety rectifier it would seem.

However nothing for a 2N633. Sure there's not an additional number at the end? I didn't try other search engines so you might have luck if you spend some time doing searches with various search engines.

It's always best to do some work on your own before you throw it to the newsgroup. You'd be surprised what you can find in only a few minutes and you develop some skills for the next time you need to find something out.

Yes, provided you are aware of what the circuit is doing.

In the usual audio stages, it will work fine. In things like
regen detectors it will still work fine, but you may need to
change feedback slightly.

Keep the voltages as low as usable, to keep from burning up tubes.

Good Luck

I've never quite understood the 'protocol' in this regard on Usenet, if indeed there is any. I know in my own case, that if a pose a question on an unknown group, then I'll watch that group for a week or so for replies.
Also, on the groups that I frequent daily, if a newcomer shows up with a question, I'll usually reply to him directly as well as to the group (its a one-button operation that requires no extra effort) unless he has a munged address which is indicative of not wanting direct replies.
I've had some people get extremely nasty about receiving a direct reply and even had one guy report me to my ISP for sending him unsolicited email...and a second time when I e-mailed him with an apology!
I don't see any reason to get on one's 'high horse' simply because a guy asks for a direct reply. He may not have usenet access at home (or know how to use it!) and have posted from his computer at work, or his buddie's computer or whatever.

Someone already took the rectifier; the 2N633 is a PNP TO-5 transistor.
Ratings: 30V, 50 mA collector current, hfe of 60 "typical" at 10 mA.
I'd try a 2N2907 as a starting point.

On the flip side, I have a full-time job. So, if I have a question, and
I know of a group that can answer it, I'm going to post to that group in
the hopes that someone will help me out. I may not have a chance to
actually go and ~check~ for responses until after my server has deleted
them as out of date. So, asking for email seems reasonabe for someone
who doesn't have the time to surf on a regular basis...

Fair enough - but, one could always post the question, and then check
back when they have time, by looking up the thread on google's usenet
archive. That way, they don't give an imppression to the group that they don't
care enough to have their question answered, yet they can still find the
information. To ease the search, one could always throw in some
fairly obscure phrase, such as "Catch the yellow furnace-monkey before
he fenestrates the entire office", or something.

Then again, that may not be as rare of a phrase as one would expect,
given the odd things that get discussed on Usenet.

If someone asks the question of the group, then the group should benefit from the discussion that results. To ask for a private reply is somewhat selfish, as well as limiting of the responses and interaction inherent in a Usenet discussion.

>

Whoa! Not so fast. My trusty "GE Transistor Manual", Seventh Edition,1964, says the 2N633 is a germanium transistor. A 2N2907 is silicon, and that's a different animal altogether. The 2N633 specs are:

PNP, germanium, TO-5 package, Pc = 150mw, BVce = 30, Ic = -50ma, hfe = 60 typ. @ Ic = 10ma, fhfb = 0.8mc (that's MHz today) type., max Ic0 = -25ua @ Vce = -20V.

GE didn't make the device, but recommended their 2N323 or 2N1415 germanium PNP alloy transistors as replacements. The NTE Replacement Guide gives the NTE 102 as the current replacement part (see www.nteinc.com), and that should be available through any of the usual sources of NTE replacement stuff.

In addition, the NTE Replacement Guide gives the NTE 5962 as the replacement for the 1N3492 diode. (The "GE Transistor Manual" doesn't mention the 1N3492.) The NTE 5962 is a press-fit silicon rectifier, If = 25A, Prv = 400V.

4786. spec sheet needed on a 3sk122

Marketplace:
Generic Number: 122
Status: Discontinued
Military/High-Rel: N
V(BR)DSS (V): 20
V(BR)GSS (V): 8
I(D) Abs. Max (A)(@25�C): 25m
Absolute Max. Power Diss. (W): 200m
Maximum Operating Temp (�C): 125
I(DSS) Min. (A): 25m
I(GSS) Max. (A): 20u
g(fs) Min. (S) Trans. Conduct.: 22m
@V(DS) (V) (Test Condition): 6
C(iss) Max. (F): 6.5p
Package Style: Macro-X
Mounting Style: SURFACE MOUNT

V(BR)DSS:
Units: Volts

Drain-to-source breakdown voltage, with the gate terminal short circuited to the source terminal. Formerly known as BV(DSS).

The breakdown voltage between the drain terminal and the source terminal when the gate terminal is short circuited to the source terminal.

V(BR)GSS:
Units: Volts

The breakdown voltage between the gate and source terminals with the drain terminal short-circuited to the source terminal.

NOTE: The symbol V(BR)GSS is primarily used with junction-gate field-effect transistors. The symbols V(BR)GSSR or V(BR)GSSF are used with insulated-gate transistors having shunting diodes or similar voltage-limiting devices.

V(BR)GSSF is the forward gate-source breakdown voltage. V(BR)GSSR is the reverse-gate source breakdown voltage. Also seen as V(GS) max. V(BR)GES use this spec for IGBT transistors.

I(D) Absolute Maximum (A)
The absolute maximum dc drain current of a FET transistor measured at 25 degrees celsius ambient temperature.

P(T) - Absolute Maximum:
Units: Watts (total value per package)

This is the absolute maximum (rated maximum) power dissipation, usually at 25 degrees (C) case temperature

DSS) - Minimum (Amps) -
The direct current into the drain terminal when the gate-source voltage is zero. This is an on-state current in a depletion-type device, an off-state current in an enhancement-type device.

I(GSS) - Maximum (Amps) -
The direct current into the gate terminal of a junction-gate field-effect transistor when the gate terminal is reverse biased with respect to the source terminal and the drain terminal is short-circuited to the source terminal. For insulated-gate field-effect transistors, it may be defined as:

I(GSSF) - forward gate current, drain short-circuited to source.

I(GSSR) - reverse gate current, drain short-circuited to source.

g(fs) - Minimum
Common-source small-signal short-circuit forward transfer conductance. The ratio of rms drain current to rms gate-source voltage with the drain terminal ac short-circuited to the source terminal. yfs(real) is an equivalent.

Alternate unit: Siemens (S) - (1 mho = 1 Siemen)

@Vds {Cond For g(fs)}:
Units: Volts

Drain-source voltage. The dc voltage between the drain and source terminals.

Short-Circuit Input Capacitance, Common-Source - (Farads)

The capacitance between the input terminals (gate and source) with the drain short-circuited to the source for alternating current.

>And boy! Didn't we get a nice group discussion out of this thread!

<SIGH!!!>

Okay guys, please let's not go down this road!!!

My preference has been that if I initiate a thread on Usenet, I follow it when I can. Some news readers, like Free Agent, will allow that very easily. I've got a full-time job, take college classes and raise four kids and still find the time to keep in touch with my friends on Usenet.

My other preference is that I like to maintain a little distance between Usenet and personal e-mail. I like to e-mail people I know personally and tend to reply in public to those who I don't know well. Also, by reversing my e-mail address to avoid spam (it works, and most people who need to e-mail me figure out that the moc. is .com backwards), I lose the ability to e-mail through Free Agent. I would have to cut and paste into my e-mail program.

THIS HAS NOTHING TO DO WITH NOT WANTING TO HELP ANYONE!!!

Let's focus, instead, on Mr. Reeves' needs and drop the other issues. I'm sure he will look back at the NGs when he can.

Steve

> replies.

It's this simple: These are Usenet *discussion* newsgroups. Any answers to "your" question may be interesting to others. Question here, answer here.

It's just downright rude to drop a ploppy like "I'm too good to associate with you crumbs, but maybe you can do some work for me, so drop me an e-mail with the informstion I demand."

> Also, on the groups that I frequent daily, if a newcomer shows up with a
> question, I'll usually reply to him directly as well as to the group
> (its a one-button operation that requires no extra effort) unless he has
> a munged address which is indicative of not wanting direct replies.

In the days when newsgroup propagation could take days and articles were often dropped along the way, that was a good thing to do. Today, when nearly all servers are well enough connected to get all articles in a reasonably short period of time, you're just doubling the traffic. From my standpoint, it's aggravating to reply to an e-mail and then find the same thing in the newsgroups, waiting for a reply.

> I've had some people get extremely nasty about receiving a direct reply
> and even had one guy report me to my ISP for sending him unsolicited
> email...and a second time when I e-mailed him with an apology!

That was way off base. ANYONE who doesn't want e-mail related to his topical Usenet articles should say so in every article. It's a long-standing tradition that replies that don't belong in the newsgroup for one reason or another should be sent via e-mail, and it's as much a "rule" as any other on the 'net.

Hi

NTE equivalent for 1N3492 diode can be found here:
http://www.nteinc.com/specs/5900to5999/NTE5962.html

Equiv for the germanium PNP transistor is here:
http://www.nteinc.com/specs/100to199/pdf/nte102.pdf

[I assume you just wanted to know the spec and would search for a suitable
replacement]

Cheers

Elaine

The internet has "neuter" gender in the English language. Why don't you check a few modern Spanish, German and French grammar books, if its 'gender' is so important to you? The internet also has a lot of "sex", but you're probably in the wrong part for that...this is the "boonies" known as Usenet... ;->

This is nothing more elaborate than a simple VOX (voice operated
transmit)
relay using the police radio as the sense input. A Google search on
VOX or "voice operated relay" should pop up dozens of simple circuits.
Plenty of companies, (including Jameco, MCM Electronics, and Radio
Shack) sell kits.

I should've realized (and noticed) that a transistor that old might be Ge.
Thanks for the catch.

==========
Bill , It is probably easy to find out yourself.
What is the indicating range of the meter ? Say 1 A

If not known you can check the actual meter range without a shunt by first allowing full scale deflection in series with a digital mA/ volt meter in mA range (using a low voltage and a potmeter). You now know the meter range .

Remove digital meter from circuit ,again allow for full scale deflection and measure voltage across meter with digital volt meter (usually less than 1 volt). You now can calculate the meter resistance being V / I .

Now it is easy to calculate the shunt.

If the actual meter has a range of say 1 mA ,for a 1 A current to be measured ,the shunt can be made of thick copper wire ,perhaps 2 to 3 feet long.

Start with a 3 ft length of bare wire and with a constant (low voltage) current source ,(by using a LM317 or similar 78xx device in constant current mode) allow approx 750 mA to flow through the wire .

Now connect the meter to one end of the wire and to a lead with a crocodile clip(observing correct polarity)
Slide the croc clip along the wire until the meter shows full scale deflection.
Cut the wire at the croc clip position.
Now put a multi-turn trimpot with a total resistance of approx 1/2 to 5 times the resistance of the meter in series with the meter and connect this arrangement across the wire shunt.

While running a 1A current through the shunt with meter and trimpot connected as per above , adjust the trimpot such that meter shows full scale deflection.

Shunt can now be insulated and coiled . Alternatively you can replace the shunt by insulated wire of same wire diameter. The copper wire shunt should be sufficiently thick in order not to get warm at max current.

I have made similar shunts for measuring currents delivered by a wind generator and 2 solar panels.
Provided the shunt remains at room temp. the accuracy of the measurement should be within 5 percent if not better

You can of course also determine the length of the shunt wire by using the digital voltmeter on basis of voltage across meter at full scale deflection .

The value of the trimpot is not all that critical , on proviso it is a multi-turn type.
Mine came from the junk box.

This coming Sunday....

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday August 19th 2001
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all

sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

********** $1 buyers discount with hard copy of this notice ************

<<<<<<<<<<<<<<<<<<<<<< cut here >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

Mail the coupon below by the 5th of the month to be a Prepaid Vendor.

FLEA at MIT 2001 Rates

SELLERS

This year each vendor must have a Cambridge Vendor License.
We will do all the paperwork to get the one day Cambridge licenses.
To keep the spaces affordable we are discounting your first space.
To use your spaces the named vendor MUST be present.
Rates include one admission per space.

Advance $17 First space - includes $10 Cambridge Vendor License
$12 Additional Spaces
Must be received by the 5th of the month.

Gate Admission $20 First Space - includes $10 Cambridge Vendor License
$15 Additional Spaces
Admission is after the prepaid vendors

Early Bird Buyer -Admission after the prepaid vendor line is admitted. ~ 7:15AM
** You may not sell. **
$15 per person at the gate.

4799. austin, san antonio area swap fest

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-15 12:43:02 UTC
From: bill hennessy <hennessy@281.com>
Message-ID: <q7ue7.156$YI3.68598@paloalto-snr1.gtei.net>
Source record: 50996

The date and place has been set for the HLARC Swap Fest.
The date is September 8, 2001 and the place is the Industrial
Park located south of Burnet on highway 281.

The location has an abundance of 100 to 200 year old Pecan
trees with picnic tables and an area for BBQ or whatever.
Electricity is available along with a Pavilion.

The location has been reserved and now we need to get
the word out about this function to everyone that you
contact, any nets that you check into, or any ways that
might bring in folks for the fest.

Roy - K5WSC
President HLARC

4801. Anybody has a schematic for MRF238?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-15 19:25:13 UTC
From: Anders <anders.gavner@removethis.swipnet.se>
Message-ID: <M2Ae7.9546$5t1.18828@nntpserver.swip.net>
Source record: 50898

Hi!

Does anybody have a good schematic on a class C amplifier for the MRF238 to yield about 10 dB of amplification in the 100Mhz range? I have tried one without success (did
only achieve 12W out with 3W in).

kind regards

Anders

Be certain to have it announced on the local swapnets. 3.922, 3.870, 7.245
etc.
Send your info to Betty W5PUP w5pup@texramp.net
She can put the info out on all those nets, for weeks or even months ahead
of time.

Oh come on, most of us started as pirates, and the physics is exactly the same.

Anders' problem is probably the poor construction of the device, those SO-239s look really poor quality, using coax to connect them is a bad idea also. It would be better to build it such that the box has a plug on either end with the plug center conductors soldered directly to the input and output lands.

It is also wise to keep the high and low power 'ends' are seperated.

The coils might be a bit wrong, as might the trimmers.

The decoupling is likely poor, that looks like a MKT cap in the picture, quality RF chip caps or silver micas with the flashing scraped off and weted as close as possible to the case are the way to go.

Another thing might be just plain old power supply issues, does the PSU supply the required current? How much current is it pulling? It could be sitting there just heating the output coils with UHF oscillations.

Is the power meter reliable at VHF? Is the dummy load?

One thing I always heard, and it seems to have been the case in some of
my HF projects, is that one good zap of a power transistor will degrade
the performance. So, if you've been tinkering, curing parasitics, etc,
the transistor may have suffered some damage in the process.

I have a Bird 4410A Test Kit for sale which includes the following:

1 Bird 4410A Wattmeter, (with "N" type connectors).
1 Bird 4275-020 Variable RF Signal Sampler.
1 Bird 8065 150 Watt Dummy Load.
1 Bird 4410-2 10kW 450-2500 kHz Element.
1 Bird 4410-4 10kW 2-30 MHz Element.
1 Bird 4410-5 1kW 25-80 MHz Element.
1 Bird 4410-6 1kW 50-200 MHz Element.
1 Bird 4410-8 1kW 200-1000 MHz Element.
2 Male "N" to PL259 Adapters.
2 Male "N" to BNC Adapters.
1 18" RF Jumper with "N" Male Connectors.
1 Bird RF Power Value to VSWR Chart.
1 Bird Wattmeter Case.

All equipment is in excellent, (like new) Condition. Pictures available.

hello everyone.
I was hoping someone would be able to send me a schematic or point me to a project for a 70cm rf preamp that I could mount on my tower.

I would like to build my own. After buying the SSC electronics 2 meters preamp, I dont think it can be that difficult. Either way, hopefully someone can help.
Thanks

Yep, I've cooked a few linear ones by having the bias pot at max rather
than min before the initial tune up. "Why is it pulling 15A with no
drive? Oh *drat*!" Serves me right for not using a limited supply
initially.

4811. Interpreting a SPICE model test results

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-16 18:11:48 UTC
From: Mark Mohr <themohrs@fuse.net>
Message-ID: <tno34sqsl5sf08@corp.supernews.com>
Source record: 50908

Hello again, everyone ;

Thanks to W7EL, I have pSPICE Student now. I've been tinkering with a bidirectional amplifier model, and think I might have stumbled across something. Problem is, I don't know how to interpret some of the things pSpice is showing me. It looks very good, if I am guessing correctly where the plots are concerned. I really, really need someone to look at it and tell me if I am reading it correctly.

Has anyone out there a) got pSpice and b) the time to interpret the model ?

Thanks,

Mark

4812. Beware of Auburn Metrology Labs Inc.

Newsgroup: rec.radio.amateur.homebrew

This is a warning notice to all in radio land about a test equipment company located in Auburn, KY. They are Auburn Metrological Labs at 12345 Bowling Green Road, Auburn KY. 42206. Their number is 270 542-6000.

Based on information given to me by their General Manager, Ken Knowles, they would be able to repair my Cushman CE-50 that was having a receive problem. It generated fine and all pll were locking fine. They gave me an estimate of under $300.00 with a turnaround of about one week. I sent it to them for repair on February 24, 2001 based on this information. After a couple of months went by without even an acknowledgment of receiving it, I tried to contact them by telephone and email. Still I received no information on it and after numerous emails and a couple of letters, one being a legal demand letter, the unit showed up at my door with a 110.00 COD charge. After contacting the company I was advised that Ken Knowles was on vacation and the service manager was arrogant, rude and even hung up on me. If you value your equipment and it is in need of repairs or calibration, PLEASE do Not send it to them. You will regret it.

My options, against them, are not exhausted but I would rather have never had the problem to begin with. It has the tendency to taint all repair facilities. This outfit was recommended by a person from one of the amateur news groups. I hope I have prevented any grief for others by this post. Thanks for listening to my ranting. 73's Don Smith KB6GQA

Sorry Donald, I really do not understand your need to express your views here. As I read your post you paid $110 when they estimated "under $300". We have your side of the story and I do believe you version, but I think it is fair to have the other side. I am involved in servicing and while perhaps 95% of all repairs are straightforward, some do go wrong. I'm not really trying to give excuses, but some of the problems I have encountered include.
Leaving a message at the contact phone number regarding repair and they do not pass it on (they will never admit this later).
Wrong phone number supplied.

No response to phone calls (or message left). Please understand I may have 50 repairs at any one time and I can not call each client 5 times daily (work it out).
Email can be impossible. I often receive over 300 messages per day. How can I read or replay to them all and still have time to repair your radio?

I have also hung up on callers. Some can never see reason.
No doubt others have had bad servicing experiences, but many will have good ones. We will always hear the complaints.

Best Regards
Neville

I am fully aware of your reluctancy to give tips to a person who has only a D licence (Maritime VHF). My intention was to build one for a friend of mine who is running a pirate radio station, and one for me in order to build an amplifier for my 3W VHF radio! Since most of you probably don't believe in me I won't bother you with this question anymore. My greatest apologies for disturbing an exellent forum.

kind regards

Anders

Dear Neville,

If you are as busy as you say, you owe it to your customers - and yourself - to hire help... if only office help, to keep open the lines of communications between you and your customers.

The key word here is *service*! To do this, you must be able to take a true interest in your customer's concerns, then make every effort to satisfy them. After all, you are in the business of offering a service - not a bad experience.

Methinks the service folks who have attitudes similar to yours_are_part of the problem; it's always the *other guy's* fault - never yours. Have you ever considered the possibility that_you_may be the one who is lacking reason? In any event, hanging up on a customer is as un-professional as you can get!

In the final analysis - when your service business fails - you will have no one to blame but yourself! I hope you come to your senses before that happens...

73 de Chaos

Hello Neville,

Unfortunately, I cannot accept your justifications... obviously you either reside in a well populated area - else you would have run out of customers by now - or you exaggerate the time you've been in business... without any office help!

In no way would I work in someone's shop again... I moved past that 30 years ago when I went back to school for my degree. At that time I was the national service manager for a well known international corporation.

As far as my business background, it is extensive...

It's obvious you see nothing wrong with your business attitude, therefore I see no reason to continue this thread. Good Luck!

Go to www.nteinc.com and do a search for 2n633

It crosses to a germanium PNP

It is likely you can order it through Mouser, or just try a generic silicon
PNP

Many thanks!

The amp pulls about 1.2 amps @ 13.8 V supply. Yep, the power meter is good up to 160 MHz (maritime VHF). The dummy load should also be OK, it gives a SWR of 1.2:1

/Anders

4825. Power supply amperage?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-17 10:58:46 UTC
From: The Dude <surfer@smurf.net>
Message-ID: <3B7CF8AD.4981D4C7@smurf.net>
Source record: 50922

I would like to know the formula for calculating the amperage that my power supply is drawing from the wall outlet. For example if the supply puts out 12VDC and the current draw is 8.5 amps how much is being drawn at the 120VAC side?

Thanks!

P.S. This is a switching power supply in case it makes a difference.

You can only estimate it because it depends on the efficiency of the power supply. 12V x 8.5A = 102Watts - thats the power taken from the supply. If you "assume" 50% efficiency then the supply draws 204Watts from the line. 204W / 120V = 1.7A.

You should get a bit better than 50% efficiency...but it depends on the design. A handy way to check, if it has a fuse on the AC side, is to pull the fuse and place your VOM ammeter across the fuse contacts. That way you don't have to disturb any wiring.

I've seen quite a few. Since I work in cable tv, we use them quite often
in the field to measure the AC current on a cable during
troubleshooting. I've gone DMM these days so I'm spoiled and can't
quote any specific model numbers.

Neville,

I think you miss the point. If the person doing the service quotes that the work will be done in a week or whatever, then misses it by a factor of 10, then the person did not live up to the agreement. The man's point is correct, you are in a service business. Deliver the service that you commit. If you tell people if will take months at half the price, then so be it if that is what they accept. No one appreciates a commitment that cannot or is not, delivered. And yes, in some cases, I would pay more to receive good service. Poor service at half the price is no deal in my book.

54ft Tristao (United) crankup, Mosley TA-33 Tribander, CDE Ham II Rotor;
2M Ringo Ranger. 10ft mast. With cables, hardware and approx. 200ft new
RG-8.

All in good working condition and currently in use.

All for only $400, but buyer must take it down. Located near New Haven, CT.

Mine worked on 10 meters in 1948! But it was a constant battle taming parasitics. I would suggest that you find a layout/project that someone has already built and debugged.

Of course, mine was operating Class C with grid drive - maybe a grounded grid arrangement will "play nicely with the other children."

I would expect that the tube output capacitance will be a major problem on 6 meters relative to tank circuit component sizes, etc.

You will need a True RMS amp. meter.. because the amp. drawn from the
outled is not constant or sinus shape.. it comes in burst evry
periode/two times a periode, to recharge the Main Cap.
a littel drawing:

```
/\ /\
----/ \-------/ \----- And so on..

|------60hz-----|
```

btw. what is a VOM meter? if it is the same as True RMS, then, DOH!

Kind Regards
Jan Rasmussen

Some useful hints and practises for designing critical input and
output circuits for operating a valve on higher frequencies than it
was designed for may be found reading the following article W2AIH
Carmen F. Moretti "Improved 5894 Amplifier for 432 MHz" QST July 1969
p.30
The ideas may apply for 6m amplifiers using low frequent valves like
6KD6, EL509, PL509, 813 and many more

Technical correspondence (QST) used to be good for discussing such
ideas until early 80's. I remember having read a few similar notes but
cannot remember any references now.
Radcom (RSGB) technical topics once mentioned that a sweep tube had
been used on 6m using special design, but didn't show the details

The QST article is available on CD from ARRL HQ.

4849. broad coverage receiver design

Newsgroup: rec.radio.amateur.homebrew

Source record: 50946

Hi

Is anyone aware of a single coversion receiver design like that
of the K2 elecrafter which provides frequency coverage upto
about 200 MHz ..

I have been hunting for a new rig and it seems that the K2 has the best
performance metrics for imd .. even compared to the commercial
options ... only problem is I would like to include 6 M coverage and maybe
2m ..

I suspect that some of the imd performance is obtained by the use of
the bpf prior to conversion ....

Thanks

Stephen

It's really not possible to design what you're asking for.

First, if you want a receiver with general coverage, without any holes, the first IF frequency has to be outside the range of coverage of the receiver. So your first IF would have to be above 200 MHz.

Furthermore, a receiver that covered up to 200 MHz, even with coverage holes, would have to use a fairly high first IF to have acceptable image rejection. If you used a 4.9 MHz IF like the K2 does, the image would only be 10 MHz (approximately) away; unless you used an elaborate front-end filter (and it would have to be tuned, since you're asking for a general-coverage design), the image rejection would be poor. Even the 10.7 MHz first IF used in a lot of VHF radios is not ideal in that regard.

Your next question: why not have more selectivity at the first IF of your general coverage receiver (which we have already determined will have a first IF above 200 MHz)? It would be a good thing to have - but it's very difficult to achieve at that frequency. The usual sort of crystal filters, for example, won't work. Cavity resonators might do a nice job, but they're much too big to include in a typical receiver design.

Still, it's possible to design a multiple-conversion receiver with high dynamic range. (The Yaesu FT1000 manages the trick, for example.) The first and second mixers, the post-mixer amps, and the RF preamp (if used) must all be very strong. Of course, this also means that they will consume a lot of power (in general, the larger you're willing to make the standing currents in an amplifier or mixer design, assuming you use devices that can

handle the current, the larger its dynamic range will be), so it would not work well in a design that was intended to run from batteries.

Hi,

I realize this isn't a direct answer to your question, but here goes anyway.

Probably your best bet is a pair of outboard converters to cover the two and six meter bands. They would not have to be very complex or very large. Three transistor designs do a good job and are easy to build. You might be able to build them in a fashion that more or less fits into the K2 housing. The net result would be a double conversion rather than a single conversion radio.

A K2 on two and six will only do SSB and CW. Most of this action is in a small part of the band and depending on your location fairly sporadic. Over here at least most VHF stuff is FM and I would recommend only doing that with a radio designed for FM. Try the converter approach to see if you can hear anybody before you get to deep into it financially.

Hope that helps.

Karl---

> this is not a real question for amateur radio but i hope to get some
> help here.

I assume that these were both HF antennas? What were their
specifications? Were they vertical or horizontal? Center, off-center,
or end-fed? Did they have a preamp?

My suggestion would be to get a copy of the ARRL Antenna Book, and read
on antenna theory. You can then determine what is best for you. In any
case, if you are simply recieving, a half-wave center-fed dipole cut for
the lowest frequency at which you will be listening, raised at least a
quarter wave above ground, will work quite nicely. There will be some
minor directivity (nulls in the direction of the wires), but it will
give you a good starting point. Also, a vertical antenna with quarter
wave ground radials, again cut for the lowest frequency to which you
will be listening, will work well.

My station at home (amateur) uses an off-center fed dipole with the
short leg being about 10m in length and the long leg being about
35--40m. I run it through an MFJ antenna tuner, and it does well both
for transmitting and recieving.

If nothing else, a random-length end-fed wire will work, the longer the
better.

Good luck,

Henry C. Gernhardt, III

Remember that most VOMs (Volt-Ohm-Meter) only measure DC current, not AC.
An AC ammeter will be needed. Also implied, but not stated, is that the
power supply should be fully loaded when taking this measurement.

When in an actual circuit there's no difference between a grid-leak
resistor and any other sort of resistor of similar wattage and
value. It is merely the circuit location which gives it its name.

But if you insist on lookalikes of pre-1940 radio resistors start
looking at the very bottom your grandad's junk box - if it is
still collecting dust in that attic. They are the solid-carbon
variety with body-tip-dot in different colours.

Source record: 50854

Are you sure you need a new audio IC? I once thought I did, but finally figured out that the audio on the HW-7 was designed to drive high impedance headphones. Instead, I simply added a 1000 ohm to 8 ohm audio transformer between the headphone jack and the audio output.

If it really was bad, I am sure that it could be bypassed and modern low noise op-amps such as the NE5532 could be used in its place.

I would look for another junk box. The 813 would be VERY inefficient at 50 and would have to be grid driven, the output of the Ten Tec would not be any where near enough to drive it in a GG configuration. You would probably get as much out of a 6146 as you would out of the 813. Look around for a 4X150/4CX250 family of tubes, they are very good on 50 even though the power supply/blower requirements are a bit more demanding. If you ask around you can probably find someone to give you one. The older ARRL handbooks featured a very simple 50 MHz rf deck and the Ten Tec would drive it nicely.

I came across an mrf838A for a buck the other day. I've done a couple of searches for this device on the web, and it's almost as if it were never manufactured, except for 1 or 2 references and the fact that I have one.

Since it's an MRF series, I checked at Microsemi...I guess they only list datasheets for current devices [I'm guessing that's standard practice]. While I wait for the free trade zone to process my registration, does anyone know where else I might find a datasheet [or simply the S-parameters]? Are there other 'consolidated datasheet sources' online [other than manufacturers websites?].

I hope this hasn't been asked recently...thanks for any help.

4865. Tempo 2020 no rx - asking advice

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-18 22:26:16 UTC
From: Alan Eldridge <alan.eldridge@dragonbbs.com>
Message-ID: <3B7EEB88.6DEF03C3@dragonbbs.com>
Source record: 50862

Got a Tempo 2020, details I'll explain in a minute. I'm interested in hearing
if there's any 'lessons learned' or anyone who's been there before on this problem to save me re-inventing the wheel.

Problem, no receive. Good audio, static, hold a signal souce nearby and hear it, but radio does not tune. I also (sort of) hear off-air signals, but
again, radio does not tune.

As far as I can tell for now, it's the PLL Unit board. I've got a good signal
(looked at it on the o'scope) on the internal VFO, but there is zip, zero,
nothing on the VCO out. I also verified on unplugging J105 on the local

oscillator unit - nothing happens, which also confirms to me the PLL board's
deadness.

Anyone every torn into one of these? Looks like it's a real pain to even get
out, let alone trying to get into for test points.

Reason I have this radio is one of our club members bought it by the table
at Dayton, said it was dead, he didn't want it anymore, sell it if we could for
money for the club. I wanted to try to get it going first, if at all possible.

Reply here or via email. Thanks if you can help.

In those days, there were no components with 'leads', so I would guess it was simply the way of the era. I have read some texts where subbing in different values could be tried to peak performance. In my experience with '01As, its pretty moot tho.
Its hard to find good ones these days and alot of folks simply unsolder the ends and stick a little 1/8 or 1/4 watter inside. Some of the original ones seem to be something like a strip of paper with pencil carbon smeared on it!

I don't think it was so much failure as it was easy substitution of
different values so as to obtain smooth operation, especially as
regenerative detectors and varying B+ voltages were in vogue. Also, many
sets used them to stabilize the load on transformer-coupled audio stages to
prevent "howling" as one approached "critical mass". Do I begin to sound
like an expert on things that nobody wants done any more ?? John S.

I'm making an attempt to design a power amplifier using a MOSFET and I'm starting to notice an odd trend. When I perform the stability analysis using the s-paramters (large signal s parameters) and the following equation:
K = (1 + |(S11*S22 - S12*S21)|^2 - |S11|^2 - |S22|^2)/(2*|S12|*|S21|),
I am finding that nearly every MOSFET I look at is not stable over most, if not all, of it's usable frequency range.

I am quite certain that, since I am not the first person to look at this, there is probably some reason for this. More importantly, there are probably some implications that this has on the design process using power FETs (i.e. feedback and/or neutralization).

Is there a reason *why* FETs are not stable, according to the equation? Are there any specific types of remedies that are more effective than others? Is this a dumb question?

Thanks in advance.

Hi,

Basically what the math has told you is that you can't build a stable MOSFET power amplifier and run it directly out of a 50 ohm source into a 50 ohm load. Both input drive impedance and output load impedance are going to be less than 50 ohms.

A very simple way to look at it is that a power mosfet usually has an enormous internal feedback capacitor built in to it. Most circuits get around this by swamping the gate with a very low value resistance.

Since the internal feedback is capacitive your gain will roll off as frequency increases. Most designs seem to take care of this with a feedback resistor in series with a low value coil.

Exact values depend a whole lot on which devices you are working with and the frequencies you are trying to run at. Just as a totally in the dark guess, try 10 ohms or less on the gate and a couple of hundred ohms of feedback resistance.The output load will in part be defined by the supply voltage, class of operation, and expected power level. I would do the math on it and then put that load on the device.

None of this will get you a finished amplifier design, but it will get you closer than you are at the moment. Manufacturer's data on the devices in question might also help. In either case a software circuit analysis package might speed up the process.

Hope this helps.

4881. measuring 1440MHz signal with 275MHz scope?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-20 01:32:48 UTC
From: lagagnon@fakesprint.ca

Source record: 50877
Cross-posted to: sci.electronics.basics,rec.radio.amateur.homebrew

I am currently attempting to repair a faulty Wavetek 3001 signal generator. I believe one problem may be low UHF (1440MHz) oscillator output. I need to be able to measure this 1440MHz signal, which is supposed to be a 20mV P-P signal. However, I have a scope with a bandwidth of only 275MHz. On the scope I do see a signal there, but very low signal strength and a distorted waveform. I don't trust what I'm seeing on the scope due to bandwidth restrictions of the scope. Is there any other way of getting a rough idea whether the oscillator is putting out a reasonable signal or not??

I seem to think that the signal might be just OK because the signal generator is working on most frequencies, but does not lock on signals in multiples of 40MHz, also one of the PLL loops leveler circuit reads a very high voltage which suggests to me low signal input from the UHF oscillator.

Any ideas out there would be appreciated.

<ON LIGHTBULB>
Ahhh! That would explain why the large signal 'data' for MOSFETs always
lists "Gate shunted to ground via x-ohm resistor" (for common source amps).
I was always curuious about that...now I know. This would also explain why
power FETs like the IRF5xx series are so difficult to tame.

> Since the internal feedback is capacitive your gain will roll off as
> frequency increases. Most designs seem to take care of this with a

And this goes to answer yet another question that I had. You're batting 2-2
so far. About 6 months ago I posted a question (I don't remember where) in
regards to the purpose of the R-L feedback, but got no help [I guess it
wasn't on this NG (hihi)].

> Hope this helps.

More than you might know. Thanks Bob.

They'll be rare if you find them. One possible avenue is to find an OLD
TV parts distributor and see if they might have an ECG 785 or NTE 785.
That too is a discontinued part number, but someone who's been in the
business for a really long time might have one in the cracks.

Since the input waveform in periodic, the several decades old principle of an analog sampling oscilloscope could be used. The input signal is sampled at a slightly different frequency (say 1400 MHz) or some submultiple (700, 350 .. 140 MHz) and the aliased output is viewed with any conventional oscilloscope. In addition to the sample clock generator a sample & hold circuit is needed with a very short (less than 100 ps) sample time.

In this way, a single sample is taken from each sample (or nth sample if submultiples are used) and the sample point moves later and later on the RF waveform and a complete waveform (the alias) can be constructed. The same principle is used in modern "digital" receivers, when the band limited analog IF signal is undersampled in order to get the baseband signal.

I guess this does not help much, unless you have a suitable sample clock generator and can find a suitable S/H IC.

The right way is to measure RF levels is to use a spectrum analyzer. I suppose you don't have access to such as equipment and I don't think a 275 MHz scope can be very useful.

A 20 mV level is probably too low to get a suitable indication with a standard RF diode and a meter.

As very low cost, L band, selective voltmeter, maybe you could try to use a standard satellite receiver, which has a suitable range (950 MHz-2100 MHz). Don't forget to disable the DC component at the input of the receiver (remote power supply of the LNB) to avoid big problems ! The input impedance is 75 ohms. I hope you don't need a higher impedance input !
I have published a project to evaluate the relative RF levels with this kind of equipment :
http://perso.wanadoo.fr/jf.fourcadier/television/Smetre/Smetre.htm
(sorry still in french, but will be translated in the next few days)

The previous message was sent incomplete by mistake - mouse
trouble.

To check for RF level at 1440 MHz you could use a radio scanner
that works at the frequency. Should produce a very strong response if
connected direct and a weak one if picked up on the antenna at close
range. Also a good frequency counter should lock on 20 mV, better
check the specs first.

Lots of luck!

Regards, Phil

Gents,

I'm an amateur rocketeer, and need to set up a radio
tracking device for locating high power rockets. I have a scanner and 70
cm yagi that work great on FM. Unfortunately, I'm having trouble finding
a small transmitter module to suit my needs. The US distributor for
Radiometrix has a minimum order for their modules, and I just have no
need for 100 or more transmitters. I've found a Canadian company that
has transmitters, but they say that their modules employ "ASK"
modulation, instead of FM. Can someone enlighten me about this? What is
"ASK"? Will I be able to receive and track the signal from this xmtr
with my FM scanner? These are 8 mW, postage stamp sized modules, and
would be great for my needs, if I can receive the signals.
Does anyone know of a source of Radiometrix TX2 modules,
that doesn't require a minimum order? I could use a half dozen of them.
Thanks in advance for any and all help.

==========
ASK = Audio Shift Keying ,which signifies the type of modulation , not
necessarily the mode of RF transmission.

Packet radio on VHF is usually FM transmission with ASK 1200 Baud (1200
& 2200 Hz)

Suggest you go back to the potential supplier and enquire about the mode of
RF transmission .

If FM your are in business and probably be able to use a Packet TNC on the
rx side .

It may not be the most accurate method, but you could use a communications receiver that has an "S" meter and compare the output at a lower frequency that can be accurately measured by the scope (say, 150 MHz) and then at the frequency of interest.

An RF millivoltmeter (Hewlett-Packard and Millivac are both excellent brands and you may be able to find working models on ebay) is the instrument of choice for measuring voltages at extended frequencies and are much less expensive and much easier to operate than a spectrum analyzer.

I believe that the hp 410x series of multimeters are capable of working at least into the upper hundreds of MHz, but like the RF probe idea, your 20 mv may be too low for a decent meter swing anyway.

>bandwidth of only 275MHz.....

Hi, Larry,
If you need this very badly, you probably have by now found a way
to get the proper test equipment; otherwise try this method of
frequency measurement:

Set up a pair of "Lecher wires" which is a length of transmission
line with a sample of the signal you're trying to measure on it
as a standing wave. At 1440MHz the wavelength is about 8 inches
so you could take a piece of TV twin lead about 2 feet long, shorted
on one end and excite the other end (unbalanced) by coupling one side to
your signal and the other to ground. Now the problem is detecting
the signal but I think a Schottkey diode detector connected to
a sensitive DVM or even 100uA meter would allow you to detect
the RF on the line. Knowing the distance between standing wave
voltage nulls on the transmission line and the wave velocity (with 300
ohm twin lead, v=.85c=10.0in/nS) you can calculate the
frequency because the distance is a half-wavelength:
f[GHz]=5.0/D[in.]. So if the spacing between voltage minima
is 3.58inches, for example, the frequency is 1.40GHz. Using bare
wire in air dielectric would give you better accuracy because the
velocity is known better (11.8inches/ns).

The Ramsey 2 meter amplifier kit uses an MRF-238 with inductors you make per the kit. This kit lends itself to experimentation quite nice. I've already done it myself.

Real world, about 4-5 watts in gets about 30 to 37 out, don't forget to add some type of filter on the output.

cheers

Hi Jim,

Two ways to solve your problem, both work. I saw the replies from the other guys, looks like they didn't key into the work filament winding. So I'll assume your working on some type of rf amplifier project.

Yeah, the 33 ohm resistors work, but the value is kind of high. Many projects like the classic single 811a amplifier shown in the ARRL Handbook of years past use lower value resistors like 10 or 25 ohms. All you have is a bit of wasted heat if your filament transformer can take the slight additional resistor load.

The better and second way to do what you want is to simply parallel another lighter duty xmfr that has a working ct. Then use the second xmfr CT for your required connection and your set. I put an NE-2 type ac indicator on the second xmfr primary just to show it's on, working and life is good.

There's a design problem with amplifiers like the SB-200 where a glitch can hose the transformer by feeding near 200 VDC back through the filament. This is sourced by the TR relay supply and can be "fixed/prevented" with a simple mod.

Hope that helps

The right way is to measure RF levels is to use a spectrum analyzer. I suppose you don't have access to such as equipment and I don't think a 275 MHz scope can be very useful.

A 20 mV level is probably too low to get a suitable indication with a standard RF diode and a meter.

As very low cost, L band, selective voltmeter, maybe you could try to use a standard satellite receiver, which has a suitable range (950 MHz-2100 MHz). Don't forget to disable the DC component at the input of the receiver (remote power supply of the LNB) to avoid big problems ! The input impedance is 75 ohms. I hope you don't need a higher impedance input !
I have published a project to evaluate the relative RF levels with this kind of equipment :
http://perso.wanadoo.fr/jf.fourcadier/television/Smetre/Smetre.htm
(sorry still in french, but will be translated in the next few days)

I am currently attempting to repair a faulty Wavetek 3001 signal generator. I believe one problem may be low UHF (1440MHz) oscillator output. I need to be able to measure this 1440MHz signal, which is supposed to be a 20mV P-P signal. However, I have a scope with a bandwidth of only 275MHz. On the scope I do see a signal there, but very low signal strength and a distorted waveform. I don't trust what

I'm seeing on the scope due to bandwidth restrictions of the scope. Is there any other way of getting a rough idea whether the oscillator is putting out a reasonable signal or not??

I seem to think that the signal might be just OK because the signal generator is working on most frequencies, but does not lock on signals in multiples of 40MHz, also one of the PLL loops leveler circuit reads a very high voltage which suggests to me low signal input from the UHF oscillator.

Any ideas out there would be appreciated.

Rick:

On a capacitor or choke input filter run without much load, the output voltage will approach the sine wave peak voltage = 1.414 times the RMS secondary voltage. In this case, with 240 volts RMS on either side of center tap, the rectified and filtered DC voltage will be close to 340 volts with no load.

In practice the audio section will be conducting and placing a load on the power supply so the internal resistance of the 5Y3 and the choke will drop the voltage somewhat.

I notice that in the design you found the full HV DC voltage will be on the headphones you place over your ears...I hope you use a well insulated set of phones.

Hi Rick,

There should be about 300 volts on the input side and about 280 volts on the output side of the choke. A lot depends on the DC resistance of the choke.

I know someone who has some older tubes for sale that are supposedly good. The particular tube in question is a 01A, and while the filament checks out, well it checked out at 3 ohms depending on how I held my meter leads on it, at
least it is not open. I had no way to check the conductance???. Anyhow, this guy says it was checked out several yrs ago and I want to believe him but while examining the tube I could hear a tinkling sound like there was broken glass in the base, it sounded like a lightbulb with a broken filament does when you roll it around. I did not shake or rattle the tube but you can hold it on its side and roll it over and hear the noise.

The getter pretty much covers most of the glass but I could see in well enough
to tell that nothing in rolling around or broken in the envelope, the noise is
definetly in the base.

Do some old tubes rattle like this or has the envelope been compromised???

Are there any ways I can check this tube??? I am planning on using it as a detector but dont want to throw a circuit together just to check this, can I rig something up with more modern components to check the tube???

Hope I am not a bother, I got this tube/20,s radio bug and may have though I am learning, and spending money, I still have a ways to go

thanks in advance for all replies

Assuming you mean the DC voltage, it should nearly equal to the peak AC
of each half of the secondary. IOW, about 1.414xRMS or 340 volts DC.
There is always some loss in the resistance of the tube and the
resistance of the winding, so the actual value will be a few volts less,
perhaps around 320-330.

There will be a small drop through the inductor depending on current and
winding resistance, so the output side will have a little less voltage
than the input side. Ohms law will help you figure that one out.

What you have here is known as a capacitor-input filter. If you remove
the right-hand 40 uF capacitor, you would have a choke-input filter and
the DC voltage would be less and also the filtering not quite as good.
There are other trade-offs with capacitor vs choke input; the ARRL
handbook would be a good place to get some more information.

Date: 2001-08-21 02:09:52 UTC
From: Larry Braden <lbraden@home.com>
Message-ID: <20010820.220904.726955963.16203@source.homelan.org>
Source record: 50805

Hello all,

I need to produce 180 degree phase shift from a tube vfo at hf. My understanding is that there is a 180 degree phase shift across a coil. Does the coil need to be resonant, or will just a couple of turns do the trick? The VFO will operate from about 2-4 mhz, so I need something kind of broadband. Any ideas?

Thanks,

Larry Braden

>Do some old tubes rattle like this or has the envelope been compromised???

I have seen that very same condition on a perfectly good tube. I
suspect a piece of the glue which bonds the glass to the base has come
loose. As for the vacuum, when it is lost the getter "flash" area on
the side of the glass will turn from shiny black to a whitish gray. If
you like, take an old defective tube and break the glass. You'll see
the change in a few seconds.

The best test though, is while powered up.

Open filaments are a very common failure with '01As, so you've narrowed
the odds. As far as transconductance, its rare to find a used 01A that
would test at original specs, but old TRF sets are very forgiving of
weak tubes. Unless the seller is willing to guarantee them, the price
ought to reflect 'as-is' condition. I have many with little chunks
tinkling around inside and they are fine, so you can't assume that they
are gassy judging by that.
Best way to test if you can't locate somebody with a tester that will do
them is simply to try them in the set.
Good luck,

If you need two outputs 180 degrees apart, a relatively simple method is to use a "phase splitter" circuit, which is basically an active device (bjt/fet/triode) with equal load resistances on the cathode and plate (or emitter/collector or source/drain) with the outputs taken at the cathode and plate.

If you merely need to reverse the phase (180 degree phase shift), a common cathode (emitter, source) circuit will provide the required reversal.

Find an ARRL Handbook.

Go to http://www.duncanamps.com/psud2/download.html and download the PSU Designer program. It will help you design and analyse *all* kinds of transformer-rectifier-smoothing power supplies, including ones with tube rectifiers. Highly recommended!

Larry

Have you checked the power supply?

Only yesterday, I had a Wavetek 3001 with no lock, and the low PLL
LED indicating an error. It turned out to be a fault in the 2K trim
potentiometer on the PSU board. You can check the 7.3V ounput on the
back connector.

Good luck

Tom

Okay---but what I don't quite understand is how you find a rectified 240VRMS sinewave on the filament/cathode. Could someone clue me in on how this works? Also---would you use a simple resistor divider for the LVDC (if LVDC is needed) supply?

From: Adam Weber <adam@home.email.ne.jp>
Message-ID: <3b824230$0$2880$44c9b20d@news3.asahi-net.or.jp>
Source record: 50812

Hi folks

I would really appreciate it if someone could explain how to identify a "hot carrier diode". I have a library that would make many hams proud [but no real joy in answering my inquiry there!] and I get blank stares here in Japan when I ask for "Hotto-KalliA-DaiO-do". I'm pretty sure that: it's a Schottky; a popular choice for mixers; usually good up to UHF[?]; but is it some *particular* type of beast? What is the significance of the name?

I DID get 1SS98's and 1SS99's when I went thru the whole spiel of attempting to explain what I needed...The guy who sold them to me was the only person I spoke to here who had ever HEARD of NE602 mixer ICs...he even had an empty parts drawer labelled NE602, but reckons they're like hen's teeth...no new stock expected, ever...

When I checked the part numbers on NTE, they were described as "small-signal silicon Schottkys". That's nice, I guess, but I already had some of THOSE in the junk box...same fwd current rating, too...

I almost feel like giving-up the home-brewing...or AT LEAST switching to BEER!

I'd love to hear from anyone who can explain this, or can put me on the path to wisdom.

Cheers
Adam

4916. LCD Displays and Freezing point?

Hi Curtis

In my (limited) experience, the LCD will fare at least as well as your battery in extreme cold...this is based on those "weather-proof" film cameras I've ***tried*** to use in sub-zero conditions...the cameras worked just fine again after 10-15min indoors...I could've got the shots I wanted thru "guesstimation" [no light meter] if I'd lugged one of the old "manual" cameras with me. YMMV...

It's just a thought...

Cheers
Adam

I've heard of designers putting resistive heating devices just behind the LCD panel to allow use in very cold environments. Of course that would eat up battery life for portable use.

You could always sew a pocket in the case for one of those chemical handwarmer packets to lay against the LCD panel when you're not looking at it?

I think I understand your question. The 5Y3 rectifier is a double diode. The filament/cathode is the common cathode and the plates are the anodes. Current can flow only one way through the diodes. The waveform at the cathode is not 240v RMS sinewave but rather rectified AC pulses with a peak amplitude of about 240 x 1.4 volts. You can redraw the circuit (and in fact rewire it) with two solid state diodes with their cathodes connected together and their anodes connected to the transformer windings. Current can flow only when the diodes are forward biased. i.e. when the anode is more positive than the cathode. As the AC changes polarity first one and then the other diode will conduct. Does this help?

I'm not sure why you are puzzled but look at it this way.

The tube rectifier is just like having two solid-state diodes connected cathode to cathode. Maybe you're having trouble with the fact that the rectifier filament *is* the cathode. The filament supply (5 VAC) is floating with respect to ground so the voltage on the filament is simply the peak value of the half of the secondary voltage less resistive losses and the more-or-less constant drop across the tube.

Lower voltage DC can be obtained from a resistive divider with all of the attendent problems of resistive dividers: poor efficiency, poor regulation, etc.

Much of the stuff there is pretty antiquated. The
preamp designs, in particular, are obsolete. If
that's all you want, save the hassle and use a MAR 6
instead.

A better bet might be the N6CA MGF1402 design reproduced
in various ARRL books.

Room temperature units are rated 0 to 50 degrees
operating, -20 to 70 degrees storage.

Extended temperature units (negative LCD bias) are
rated -20 to 70 degrees operating, -30 to 80 degrees
storage.

Just how cold do Michigan winters get? Anybody outside
in -30 degree weather probably has other concerns...

Schottky and hot-carrier diodes are the same thing. 'Hot carrier' refers to
the conduction by majority carrier, giving high speed.

Current will flow only from ground, through the radio circuit, to the filament and then to the plate, not vice versa. Thus at the filament, you have only a positive voltage - DC.

BTW, if you are new at this kind of thing, you might be confused by people who believe that current flows from positive to negative. It doesn't, but some folks were taught that in error and they are quite persistent about it. Just ask them to explain conduction in a vacuum tube and you'll see they can't. The original mistake about current flow was made by Benjamin Franklin and has continued ever since.

Not trying to start a flame war over this, but I've been down this road any number of times and it never ceases to amaze me.

Laura:

Probably not a cold as yours get. We are at 42 N versus your 49 N.

I have yet to see minus numbers Fahrenheit. We are launching rockets
in farm fields in 0 to 20 degree weather. Clear and cold. I was curious
if my Broadcast Warehouse FM transmitter was going to crack a display in
the
field. I would assume a room temperature unit is applicable to the
installation I have.

If 0 to 50 degrees is in Centigrade/Celsius then I am in trouble. I
will have to keep the unit above freezing.

If 0 to 50 degrees is in Fahrenheit then I am ok.

Which unit of measure is it?

Thanks

AFAIK hot carrier diodes are Schottky mixer diodes. I wonder
if you are making a mixer for HF. I never found any advantage
to using 'proper' Schottky mixer diodes at HF. I usually use
silicon diodes like the 1N4148, 1N914 etc..... It might be
a different story at VHF/UHF.

I know what you mean, I took my degree in physics where we are taught
negative to positive but I roomed with EE majors who are taught just the
opposite. It made for a few good arguements until we figured out what was
going on.

Sorry, that may not have been that clear, I mean voltage on each side with
respect to *ground* not voltage across the inductor.

Yep, I got a similar response from Harold, W4PQW about the earphones. I have a very nice set that I purchased from Fair Radio Sales about 2 years ago. I've used them on a couple of minimal regenerative designs and they worked well. But in this case I've got a couple of old audio transformers that I got from some old BC tube radios that I'll be using. Safer and easier to interface to modern headphones and amplifiers

Is there some way to clean the trash messages that get dumped into these user groups? Is there no filters that can be set to eliminate the space this stuff takes? If it could just be routed back to the sender, there would be less sending of it.

George,

My name is Steve, my call is AB5MM and live south of Greenville, Texas.

I've seen your post in the "homebrew" news section from time to time and thought sense we were so close together, I would drop a line just to say hello.

My wife is a ham also and we both like code. We have a daughter that is 8 years old, but, sorry to say, she has shown no interest in radio what so ever.

Well, I don't want to take up a lot of your time, so see you on the net sometime. Maybe we can compare war stories or RF burns!

73s,

Steve

> If 0 to 50 degrees is in Centigrade/Celsius then I am in trouble. I
> will have to keep the unit above freezing.

It was degrees C, 0 to 50 is 32 to 122 in degrees F. Down here in Texas where the inside of a car in summertime is usually around 150 degrees F the display will go solid purple. Once the AC cools the car down the display will return to normal, with the exception of the areas that are now permanently dark. Where my reletives live in WI they normally get down to -40 F in the Winter with a wind chill down to -70. The radio won't work at those temps at all. My htx-202 will start buzzing below 40 degrees, this is independant of what the battery and display are doing.

If you want to experiment try putting the radio in your freezer, it should be set to about -10 F, it probobly won't work at all, so you won't have to worry about the display not working.
thanks, John.

NOW AVAILABLE

Two New Programs "DIFFRAC1.exe & DIFFRAC2.exe"

Radio propagation by diffraction over obstructions.

DIFFRAC1 covers diffraction over one obstruction and DIFFRAC2
covers diffraction over two successive obstructions.

If your QTH is stuck in a hole or in a valley surrounded by
mountains, getting out of it over the tops may not be as difficult
as you think.

Or if you are in the street on one side of a city building block
and you wish to communicate with the other side at 2GHz what power
or antenna gain do you need?

These programs may not be exact but they will put you on the right
track. Who cares about a 6dB uncertainty when the next vehicle
passing by knocks 20 dB off the signal? Or does it put it on ?

Download in a few seconds from website below.

If you're talking about spam, you can set up your killfile filters to
reject certain subjects containing XXX, $$$ and other commonly used spam
words.

Also, be sure you never, never reply to a spammer telling them to
"remove" you from their mail list. By doing so, you just confirm your
email address and even worse, that you ACTUALLY READ that stuff.

I think spam is gradually diminishing anyway. I don't use the filters
myself and I only get two or three a week. A few years ago it was
dozens.

Hope this helps.

Not hardly! It's 6 p.m. and I've received eight so far today, with 10-15 per day being average. These result from having a web site and posting on only a couple of newsgroups. Anyone who thinks spam isn't alive and thriving should drop by news.admin.net-abuse.email.

I emphatically second Bill's admonition to NEVER reply to spam, including a "remove" list, unless you want to dramatically increase the amount of spam you get. As Bill says, its purpose is solely to determine that your address is valid and active. One way to fight back is to make use of SpamCop (http://www.spamcop.net) or a similar service to determine the spam's originating ISP and send a complaint. Conscientious ISPs will shut them down. Spammers just hop from one ISP to another, but being continually shut down makes life rougher for them. I report all spam received.

Hi Eamon

There is total confusion around the place. I've seen the expression "hot carrier, or Schottky diodes" implying that they're all the same beast, in other places that there is some "special kind of Schottky" which is, acts as, or can be used as, a "hot carrier" diode. Needless to say, there is NEVER an explanation of what that is supposed to mean...[People think hams use 'jargon', but there are hundreds of tables of references as to what ham-talk means and, as far as I can tell, it is used consistently...in electronics it's a different story...]

An HF mixer is the goal. I've read the statement that "...you COULD try 1N914's, but...". At another place, there was a very stern prohibition, all capitalised, against even THINKING about 1N914's for a mixer circuit...there are even a few folks who reject the usefulness of diodes for mixers at all. Sure, they might be extremists, but it gives you pause to think, when all the really ***interesting*** receiver projects use IC mixers...

It seems that, at almost every RF stage, I'm going to have to do a LOT more experimenting than I had intended. [Oh well, I've got NO worries about the AF amp section...LOL!]

Thanks very much for the input, Sir.

Cheers
Adam

Source record: 50840

Whatever advantages Shottky diodes might have in mixers, they're not significant at HF in typical mixer use. You won't be able to tell the difference between using Shottkys and 1N914s in an HF mixer, except the necessity to drive the mixer a little harder to turn the silicon diodes on.

Yes, a lot of receiver projects use IC mixers, due either to ignorance or a conscious desire to sacrifice performance in favor of simplicity. Very few IC designs can deliver the signal handling capability of a diode ring mixer.

The term "hot carrier diode" isn't simply ham jargon -- you'll find it in numerous professional publications and texts, although "Shottky diode" seems to have become more common as time goes by. They are exactly the same thing.

I highly recommend Hayward and DeMaw's _Solid State Design for the Radio Amateur_, and Hayward's _Introduction to Radio Frequency Design_ for anyone interested in learning more about receiver design. Both are modestly priced and available from the ARRL. More comprehensive but also a lot more expensive is Rohde, Whitaker, and Bucher's _Communications Receivers_ (McGraw Hill).

4944. Re: Hot carrier...?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-22 02:28:41 UTC
From: Jim Pennell <No-Spam@killspam.com>
Message-ID: <9lv5erpib1@slb7.atl.mindspring.net>
Source record: 50841

Hi Adam.

Generally speaking, the 'hot carrier' or Schottky diode are indeed one and the same part.

Due to the manufacturing technique, the schottky diodes tend to match each other in terms of forward and reverse characteristics and this results in a slightly better balance in the mixer.

Which, of course, is usually considered a good thing.

Regular silicon diodes also work well, although it is a little more likely to be not as well matched and that shows up in higher LO feedthrough and so on. Usually, the slightly lower performance is not noticable depending on the application.

==========

Double Balanced diode mixers overall are a very good choice for a radio front end, since they have better dynamic range then most other types of mixers. The NE602 mixer for example, is cheap, has lots of gain, and can be overloaded easily by strong signals coming from the antenna.

Also, most IC type mixers tend to be lowband only, and don't work as well up at 6 or two meters.

There are exceptions and some IC mixers have astonishingly good dynamic range. But, by and large, the really good dynamic range IC mixers are complex designs.

Given the RF hot environment in Japan, I'd avoid the easily overloaded mixers....

==========

Anyway, a drawback to the diode mixers is that they require a lot of LO drive, +7 dBm minimum and I tend to use closer to +10 dBm.

Actually, the high dynamic range IC mixers also require a lot of LO drive. Generally speaking, to handle high input levels, ANY mixer will need a lot of LO drive.

==========

So, to answer the question, I find the double balanced diode mixer a good choice between ease of use and high signal handling ability.

Either schottky or regular silicon diodes will work fairly well.

Folks---

> I think I understand your question. The 5Y3 rectifier is a double
> diode. [...]

Here's what I don't get: There does not appear to be a DC ground reference for the cathode, unless you use the filament circuit. Also, the filament appears to short the 5VAC winding on the secondary. I can see it from the point of a center-tapped full-wave SS rectifier, but the filament connections have me confused.

So why is the filament shorted across 5VAC floating?

Also, the wiring of this circuit, with its odd (at least to me) ground configuration doesn't jive with my knowledge enough to understand how we get approx 340VDC at the 16H (16H!! I didn't notice THAT before!) inductor with respect to ground.

Thanks,

Henry C. Gernhardt, III

Hello Adam!

Parts procurement problems in JAPAN? No sympathy here OM!
I'm on Sao Miguel island in the Azores, 800 miles WEST of Lisbon.
No Radio Shack stores in sight! I also did homebrewing in the
Dominican Republic.

I recently built two diode mixers for use in a 17 meter double
sideband transceiver. In the transmitter I used two diodes, in the
receiver, four. Becasue no Schottky or Hot carrier diodes were
readily available, I just used some mystery diodes that were in the
bottom of my junk box. I tried to match resistances a bit. They seem
to work fine.

You can check out my rig at
http://planeta.clix.pt/n2cqr

I like these home made mixers better than the NE602 black boxes.

Tell us more about your project. All kidding aside, it must be
interesting to homebrew in Japan.

73 and good luck

Bill CU2JL

I don't know if I'm right, but, ...

When I saw the K2, it made me think of the R2 receiver that was
published in QST, some years ago (Jan 1993) . Its a direct conversion
receiver. It made me think: "well maybe someone finally has done a
complete transceiver kit with this excellent receiver design"

Try an internet search for the R2, by Rick Campbell, KK7B

I'm starting to get the idea, Roy. Someone kindly contacted me privately with some very interesting links that thoroughly went through those issues. I also looked over some articles by Doug DeMaw that say exactly the same as your paragraph, above. The further implications are that your next para is also right on the money. I really am starting to see the light!

> Yes, a lot of receiver projects use IC mixers, due either to ignorance

> exactly the same thing.

I was trying to suggest, in my clumsy way, that hams are the "good guys" in this gripe! It's the "general electronics" community that I was digging at...hams, naturally, have a vested interest in keeping up with general electronics and naturally will pick up the expressions, accurate or otherwise, from other groups...

I recently got hold of the Hayward & DeMaw text. It's probably what I should have read FIRST! I'll be looking out for the other, too. I sincerely appreciate the information and your time, Sir! Best wishes. Adam

|Here's what I don't get: There does not appear to be a DC ground
|reference for the cathode, unless you use the filament circuit. Also,
|the filament appears to short the 5VAC winding on the secondary. I can
|see it from the point of a center-tapped full-wave SS rectifier, but the
|filament connections have me confused.

I thought we had this explained. The DC ground reference is the center tap on the HV transformer secondary. The filament doesn't "short" the 5V winding, it is *powered by* the 5 VAC. The 5V winding, that has--no surprise-- 5 VAC from end-to-end is also at a potential of whatever the DC voltage is, with respect to ground.

You shouldn't have a problem with this, remember, you are willing to clamp a set of headphones between your ears with the same DC potential floating on them. Same situation... an AC signal being coupled magnetically by transformer action while in the presence of a large DC bias.
|
|So why is the filament shorted across 5VAC floating?

Asked and answered.
|
|Also, the wiring of this circuit, with its odd (at least to me) ground
|configuration doesn't jive with my knowledge enough to understand how we
|get approx 340VDC at the 16H (16H!! I didn't notice THAT before!)
|inductor with respect to ground.

It's been almost 45 years since I took my Novice exam, but I think there was a power supply question in it and I'm sure you had them in your exam.

Reduce this problem in your mind to a 12 VDC supply using solid-state diodes. Forget the 5 V and 6.3 V windings and instead of a high voltage secondary make it a 20 V, center-tapped secondary. Draw a simple circuit with a single filter capacitor. When you figure out how this operates, come back and ask more questions, if you really need to.

Hi Jim

Thanks a lot for the info. I now plan on using "matched" diodes, checking the resistance from anode to cathode. I hope to find a matching set for a double balanced mixer. I didn't have much luck with matching regular silicon diodes [and had also been reading too much that praised the "uniformity" of the components formed on ICs!] but expect it will be easier with the Schottky's to find a close match.

The +10dBm for the LO sounds like a good target, too, from what you and others have said.

Thank you, Sir, for your time and energy in straightening out these issues!

Best wishes
Adam

Hehehehehehe! Hi Bill

I can understand where you're coming from, but I have to wonder if you've ever been to Japan! There are no Radio Shack stores here, either. Nothing even vaguely similar. I lived in Australia for many years, always in envy of the Americans who just seemed to have everything available, but at least we DID have a couple of nation-wide electronics chain stores, with catalogues and branches in suburban areas. There is NOTHING like it here.

We do have "Electric Towns" in the two largest cities. Sections of the cities of Akihabara [Tokyo] and Nipponbashi [Osaka] are devoted to all things electronic and electrical. There are huge multi-storey computer shops, but the components business is still run on feudal lines [Yakusa-controlled I'd bet!] There are tiny little stalls [4'x4' floor space] where you can buy the standard range of resistors and capacitors INDIVIDUALLY(!) from about 20¢¢ to a few dollars each...another guy who sells knobs...nothing else--just knobs--and so on...That still might be a paradise to someone in your position, I'm sure.

The people who run the stalls, however, (with a few exceptions) have no knowledge of what they are selling. If you can't see it, you ask for it. If the guy doesn't have that part number, that's the end of the story! I regularly see Japanese guys in suits getting the run-around from these little merchants, so I'm reassured that it's not just because I'm a 'Gai-Jin'. You can't ask for an "RF PNP transistor" or an "equivalent for a such-and-such FET". If you don't know at least 12 units that are equivalent, you leave empty-handed and float around to the next stall...but, this being Japan, it's not too cool to be "different" so you can bet that a semiconductor guy is gonna stock pretty much the same stuff as the next semiconductor guy...

At least in Oz, the teenager at the counter had a computer terminal and data-books and had an interest in selling you what you needed, because he could see all the other goodies in your shopping basket and figured HE might get stuck re-shelving it all, if you decided not to go thru with your purchase!

Nice website! The rig looks very nice too...

All the best
Adam

'Hot Carrier Diode' seems to be an americanism. I see it used in a lot
of ARRL books but here in Europe, a Schottky diode is a Schottky diode.
From your comments, it would seem that this is the case in Japan too.
I don't know much about the history of these devices. Who was Schottky?
where was he? when were they invented/discovered? what were they
originally called?

When you read about HCD's they are usually referring to high-speed
Schottky switching diodes that are suitable for use in RF mixers.
Not all Schottky diodes are designed for this purpose.

> An HF mixer is the goal. I've read the statement that "...you COULD try
> 1N914's, but...". At another place, there was a very stern prohibition,
> all capitalised, against even THINKING about 1N914's for a mixer

My old 9 band HF rig has a 'dual bridge diode mixer' similar to
the circuit described in Solid State Design for the Radio Amateur (ARRL).
I used 8 unmarked generic silicon switching diodes for the mixer. I
made some measurements of the 3rd order intercept point on 80M. The
IP3 was about +33dBm - not state of the art but pretty good. It still
compares favourably with some of the best rigs on the market.

My newest rig is a five bander that has a homebrew diode mixer.
I don't have the necessary test equipment to check the IP3
on this one. I used a diode ring mixer made from four 1N4148
diodes. I haven't noticed any problems with the RX, even on
40M at night or within a few KHz of the big guns at the DX
end of 80M. The mixer is built dead-bug style on a piece of
copper PCB. As an experiment, I decided to replace the
homebrew mixer with a Mini-Circuits SBL-1 mixer module.
I found no difference at all in the performance of the
RIG. I'm not saying there wasn't any, but if there was, it
was too small to detect.

Look at the data sheet for the Philips 1N914. You will
find that it has very low junction capacitance, very fast
switching speeds, relatively low forward resistance,

and very high reverse resistance. The perfect recipe
for a good diode mixer.

******** From the Philips data sheet **********
Philips 1N914 Diode.

Maximum dissipation 250 mW at 25C

Maximum reverse voltage (PIV) 75V

Maximum continuous forward current 75 mA

Maximum repetitive forward current 225 mA

Forward voltage drop VF 1V at 10 mA

Diode Capacitance C max 4pF, Typical 1pF at 0V
****

> the really ***interesting*** receiver projects use IC mixers...

There are some very good designs that use IC mixers. A lot of
them use high-level mixer IC's like the Plessey SL6440 (now obsolete)
or the Analog Devices AD831. IIRC these devices have an input IP3
of almost +30dBm. Just about as good as my penny diodes but not
any better.

Look at Aleksander Stare's web-site for some nice designs
using the AD831.
http://lea.hamradio.si/~s57nan

Most of the designs I have seen use low cost, low power, low-level
IC mixers that were designed for cordless phones and similar applications.
These mixers offer very poor performance when compared to the humble
penny diode mixer.

Some info about the diode mixers in my HB rigs.
http://homepage.eircom.net/~ei9gq/rig.html
http://homepage.eircom.net/~ei9gq/80M_.html
http://homepage.eircom.net/~ei9gq/rx.html
http://homepage.eircom.net/~ei9gq/rx_circ.html#Mixers

I'm sure that some of the other posters to this group will
disagree with my opinions about using silicon diodes in
mixers, but those penny diodes have served me very well
in the past and continue to do so today.

> It seems that, at almost every RF stage, I'm going to have to do a LOT

Consider switching to a decent provider for your news access. Pacbell
won't cut it. (Also, you shouldn't be using your real email address in
your news postings -- you're begging the spammers to fill your mailbox
with crap.)

Try http://www.giganews.com -- you'll find that their filters get rid of
99%+ of all the spam and junk postings, at least in the non-binaries
groups like this one.

Client-side filtering doesn't work very well because the spammers never
use the same origination address or message titles. You'll need to
either live with it, or pay a little extra for a high-quality news
provider.

My Oxford dictionary of science under Centigrade advises "See Celsius"
Under Celsius it advises "...formerly known as Centigrade, changed in
1948 to avoid confusion with a hundredth part of a grade."

Canada uses feet, inches of mercury, nautical miles etc. for aviation
(both civil and military). Then again maybe aviation is not considered
'technical'?

IIRC it was Bill's TX single-balanced mixer. The output was _very_ low
until he switched to junkbox units.

In my experence, at least at HF, good old 1N4148s work just fine. I
usually don't bother to match them either, two units from the same batch
are close enough, and a small pot will do a good job of nulling out the
carrier.

I'm not familiar with the R2 but you can download the schematics
for the K2 from Elecraft's web-site. I can't remember the URL.
I'll take a wild guess: http://www.elecraft.com ?

IIRC, the K2 is a band switched, single conversion superhet
with a seven pole crystal filter. I know several people
who have built the K2 and they are all delighted with
the way it works.

The "Yo-Yo-Tenna Deluxe" is going to be featured in the Nov. and Dec.
issues of CQ magazine. So you may want to get yours now...just in case
we get back-logged. Plenty in stock. They work 40 through 2 meters.
Operation on 75/80 and 160 can be accomplished by adding single reels.
A lot of fun! Many say it reminds them of the old "Hy-Gain tape
measure" antennas of the '50's. ONLY $29.95 plus s&h.

For a photo and more details, please visit:

1N4148 is best choice below 150MHz according to some German sources
above this frequency they are found to be too slow and inefficient

I use my HT while on patrol, (up to 8 hours) and the HT is usually in an outside pocket of either my coat or pants that I am wearing. (the pants I wear at work have a "mid-leg" pocket, much like the pants that EMS personell wear)

I have not witnessed ANY problem in the Michigan weather, and also I have left the HT sitting on my seat of my truck during the winter days/nights and also didn't witness any problems with operation. In fact it seemed to work better colder. Now in the summer, that is a complete other story. Heat is more of a problem.

If you use Outlook Express to read messages, go to the toolbar and select the Messages tab, and pull down to Block Sender. That is one way to filter. This is assuming you are using version 5.XX or higher. There is a way to filter also, but haven't gotten around to figuring that out.

Source record: 50767

I have an impedance meter that uses two scope probes connected to
a homebrewed box. The box contains a sense resistor.
I want to make a cable to simulate the 10 to 1 probe I'm using.
The impedance meter has 1 Meg and 25pf input.
I want to use RG-58a coax and a BNC connector on one end.
I'm not sure about the length, 14 inches is long enough, but it may
need to be longer to match the capacitance of the original probe.
The other end will be soldered into the homebrew box.
I know I'll need a 9 meg series resistor and some tuning to make
it flat. (the unit measures up to 13Mhz)
I put a 7pf cap across the 9Mohm resistor and it was flat using the
squarewave on the scope calibrator. However I'm not sure this is
the correct way to do it. I'd like to have 15pf/10meg looking into the
probe.
Feedback Please?
Thanks
Mike

Is there anything wrong with germaniums? (Was it the 1N23A that was used in old UHF tuners?)

Bzzzzzzt! No separate cathode in a 5Y3. Only a filament.

The first power supply I ever built, way back in 1957, had one.
I remember it well. :-)

Nah! You only think that because you were born
in the valve (tube) era. If you were a solid-state
man, you would know that holes are emitted by the
anode and attracted across the vacuum space to the
cathode. Sure everybody knows that electric
current flows from positive to negative.

1. There are advantages to using double balanced mixers, which require four reasonably matched diodes for maximum benefit. Germanium diodes vary a lot from one diode to the next.
2. Germanium diodes are hard to find. I don't think any are made in the U.S. any longer, and perhaps not in the world.
3. For applications at VHF and above, germanium diodes are noisier than Shottkys.
4. It's not possible to get germaniums in a monolithic quad, or in small packages. You'll have to deal with a lot more parasitic inductance than with a smaller package.
5. Germaniums are more fragile than silicon junction or most Shottky diodes.

The 1N23 was about the best you could do in the 1950s and early '60s. But that was then, this is now.

Thanks for the explinations. I realized, shortly after I wrote my last post, that the 5VAC winding was, in fact, the PS for the filament. I thunked my head a couple of times to loose the cobwebs that were apparently gathering dust within my cognitive centers, and once reading your post, took your suggestion and drew it out as an SS unit.

My problem was I wasn't seeing the cathode as being two separate cathodes tied together electrically. Don't ask me why that was confusing me, but it was.

Now, another question: does anyone have the conduction curve of the 5Y3 lying about anywhere?

Thanks,

Henry C. Gernhardt, III

Your original post referred to a filament which heated a cathode which then emitted electrons. No 5Y3 ever had a separate cathode. Emission is directly from the filament.

There is a tube with similar ratings but which does have a separate cathode. If memory serves me right, it is a 5V4. There might be others, too.

This scheme should work ok at low and moderate frequencies with a short piece of RG-58, although you still won't be able to exactly match the response and delay of a commercial 10:1 probe if that's your objective. From the circuit under test to the cable input you'll need a parallel RC. R will be 9 megohms. The product of R and C have to equal the time constant (R times C) of the scope input, including the cable C. What I'd do is to design the circuit with the minimum amount of C possible, then if you want more C at the test point, simply add it. Start with the C of your scope input, typically 20-30 pF. Let's say it's 30 pF. RG-58 has a capacitance of 30 pF/ft, so 14 inches has a capacitance of 35 pF. Add this to your scope's input capacitance, making 65 pF. This is the total input C. For equal time constants, the C across the 9 megohm resistor has to be 1/9 this value, or 7.2 pF. The "probe" capacitance will be 7.2 pF in series with 65 pF = 6.5 pF. If you want 15 pF at the "probe", add another 8.5 pF across the "probe" connection.

At higher frequencies (or to look at fast events) or with longer cables, cable reflections will ruin the response. That's why real probes use very special, low loss, high impedance cable, and the compensating boxes have quite a few extra parts.

The time constants of both RCs involved are 65 us. So to check the "probe" response, apply a known clean step (like from a scope calibrator) and look at it at around 50 or 100 us/division. Or check the frequency response, paying particular attention to the region around 1/(2*pi*RC) = 2.5 kHz. The response well below this frequency should be the same as the response well above it.

We used to buy matched pair of 1N23G's for replacements in Phoenix missile mixers for about $100/pr. (1970's $$)

They came in nice little lead foil cylinders with crimped ends to protect them from ESD. (Yes we knew about ESD in 1970) Two of these packages would be taped together to maintain the matching.

Our Receiving Inspection department once took a lot of them out of the packages and threw them all together in a cardboard box and put them on the store room shelf.

Needless to say, this only happened one time.

I'm not sure these were published and I can't lay my hands on my tube manual but the Radiotron Designer's Handbook (1942) calls the 5Y3 a "high impedance rectifier."

In general, at low plate voltages, the current is space charge limited and follows an E ^ (3/2) curve. At higher voltages, the conduction is dependent upon the temperature of the emitter.

If you want a science project, you could measure it. Just remember to keep one hand in your pocket.

I have used the 1N34 and OA91 point contact germanium
diodes in balanced modulators.

I never felt inclined to use them in DBM's. They tend
to have large variations in characteristics between
one diode and another. They have higher resistance
than silicon diodes when they are forward biased and
greater leakage current when reverse biased.

I'm looking for it to be flat to at least 13Mhz, and I'll build two the
same length.

>For equal time constants, the C across the 9 megohm resistor
> has to be 1/9 this value, or 7.2 pF.

My 7 pf capacitor matched your calculations very close :-)

>That's why real probes use very special, low loss, high impedance
>cable, and the compensating boxes have quite a few extra parts.

Do you know what the impedance of the cable is? Also I have checked the
capacitance of automotive antenna cable and found it has 8pf per foot.
I was tempted to start with this cable but I'm looking for wearability, and
I don't know if I could get a BNC connector on it.
Thanks for the input Roy.

Hi Ed,

Smiley not needed from you.

I was working with toobs around 1937.

One of these days, if there's sufficient popular demand, I'm gonna
write a program for design of a class-A,B,C neutralized
triode RF power amplifier, taking into account the three-halves
power law of electron flow.

Just imagine how much more rapidly the radio old timers would have
progressed had the 1Gbit Pentium been invented by 1901.

Holes, of course, have an exponentially related flow.

Regards, Reg, G4FGQ

From: Henry Gernhardt/Andrea Winship <hcg_alw@earthlink.net>
Message-ID: <3B84D720.3ED636A3@earthlink.net>
Source record: 50785

Folks---

I went to go tune into the Breakfast Club this morning, and upon turning on the venerable rig aforementioned, noticed that there was no RX audio and the digital display was blank. The VFO appeared to simply be dead, as the VFO LED indicator above the display unit was not illuminated.

This unit had also shown some ``jumping'', described as a bad ground in the AF unit according to a kenwood ASB I dug up. I also noticed in the service manual where the display circuitry blanks if the PLL unlocks. Would a bad ground such as described in Kenwood ASB-0840 also cause the problem I am experiencing? Any other ideas? My test equipment consists of a DVM, and I would like to avoid the expense of professional repair.

Thanks,

Henry C. Gernhardt, III

I'm kinda wild-guessing here as it's been MANY years since I've worked on an
830, but... I'm tempted to suspect something less exotic..

The fact that the VFO LED isn't lit suggests to me that the rig thinks
you've selected the external VFO. I'm gathering from context that you don't
have an external VFO. That would certainly explain the display blanking and
the receiver not working!

Is there some kind of jumper plug that goes in the external VFO jack if you
don't have the external VFO? (might that plug have become dislodged?) If
not, some Kenwood radios have also fastened switches to the DIN jacks;
plugging something into the jack activates that switch. Maybe that switch
is flaky on the external VFO jack?

I came into posession of a few 8-pin miniature "pencil" tubes. All are used, most are still soldered into military circuit boards. Getters all still look silver. Most are Sylvania or Raytheon. Also have a few used 8-pin mini sockets. Don't know if the tubes are good or even good for anything. But you can have 'em for the postage or trade me a tube or two

I can use.

Here's the inventory:

5 each 5840
1 each 5896
1 each 5783
1 each 5687
2 each 5899
2 each 5718

Any takers?

It would make sense, but there has never been a ``dongle'' on the
external VFO jack. The only switch I can see in the schematic is S21,
and that is not listed in the service manual under the parts list, nor
can I find it on any of the boards in the SM. Digging a little further,
it's almost as if the fixe channel switch is stuck, although I don't see
how the switch could have failed closed.

From: Mark Mohr <themohrs@fuse.net>
Message-ID: <toaenei1le4iae@corp.supernews.com>
Source record: 50791

Guys ;

I've tried signing up with the qrp-l list, as suggested by many of you. However, I've run into a problem.

I got " added to list " ok, and am receiving the digests ok, but I can't seem to post. Even a message to the list manager has gone unanswered. I have tried two forms of the address: qrp-l@lehigh.edu and qrp-l@Lehigh.EDU (the one referenced in the instructions). Neither seems to work. I get no error messages regarding undeliverable mail, so it's going somewhere, but where ?

Can anybody tell me what I'm doing wrong or what have I missed ?

I have good news and bad news.

The good news is that the problem is likely to be dry grease in the bearings of the VFO. Many older Kenwood radios show this problem and regreasing the VFO bearings fixes it.

The bad news is that getting the VFO out of the 830 is a pain as you have to remove the front panel.

If you are in central FL, I can help you.

> Thanks for the input Roy.

I don't know the impedance of scope cable, but I'd guess it at around 130-150 ohms. I believe the center conductor is unplated steel or other lossy material, probably to attenuate reflections. The dielectric has carbon mixed in with it, and some I've seen has a heavier carbon coating on the outer part of the cable to reduce triboelectric effects. (To illustrate the combined piezoelectric, triboelectric, and electret effects in ordinary cable, connect a couple of feet of RG-58 to your scope, lay it on the bench, and rap it with a hammer or screwdriver handle while watching the scope.) The only scope cable I've looked at is Tektronix. My guess is that other manufacturers copy it to some extent, and some probably save a few bucks by not incorporating all the features. I've never been involved in probe design, but it's a subtle art.

I have scrounged up a big quantity of .1 uF Polyester/Metal Film caps. These, according to the databook, are equal to ceramic disk caps in all uses. These are NOT NPO caps. Made by S+M Components.

How about 50 for $3 or 100 for $5.00 500 for $20.00 (they're abt 15 cents each from Mouser) I ship in a 4 by 7 padded envelope.

These are .1 uF, 10%, rated at 250v - New Stock, on paper tape, nice long leads. Good for bypass caps I am told. That's what I have used them for.

I still have BNC chassis connectors for

25 for $12.40
50 for $21.00
100 for $36.00
500 for $138.00

I also have:

LM7808CT voltage regulators. TO220 case. 5 for $4.50
LM7812T voltage regulators. TO220 case. 5 for $4.50

Little trim caps 3-30pF I have 25 to sell. How about $8.00 for all 25 inc shipping.

Let me know if you're interested. All prices are post paid to the USA.

73

I do accept Paypal and will ship to foreign address for additonal postage.

If you want really high level mixers, you should look at some
transmitting mixers. The RSGB VHF/UHF manual had a single balanced
mixer built around a double tetrode, such as QQV02-6 or 3-20, with
typically a 404 MHz LO drive to the grids in push pull and a small 28
MHz rig feeding the cathode and a tank circuit tuned to 432 Mhz. I
guess a double balanced design could be done with two double tetrodes.

I understand that you've had experience, but that doesn't make sense to me. It seems that the display and LED would still be functional even if there were dried grease---that the VFO would have SOME output. How is it that this would cause the blanking I am experiencing?

> The bad news is that getting the VFO out of the 830 is a pain as you

There used to be a twin beam tetrode valve/tube (I think) that was popular
for high-perfomance balanced mixers.

5008. Home made Low noise broadband antenna amplifier with GaAS FET ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-24 13:30:39 UTC
From: marcje01@yahoo.com
Message-ID: <ca10ea14.0108240530.6a7d1cef@posting.google.com>
Source record: 50703
Cross-posted to: rec.radio.amateur.homebrew,alt.radio.scanner,rec.radio.scanner,rec.radio.amateur

Hi all,

I was wondering if anyone ever built him-/herself a low noise
broadband antenna pre-amplifier with GaAs FETs.
I think it must be possible to build one. Main usage for me
would be as antenna amplifier for my discone antenna.
The reason for a GaAs FET is the low noise figure.

As a example SSB in Germany makes one from 50 - 3000 Mhz
with a gain of 13dB and a noise figure of only 1.8 dB!
See e.g.:
http://www.thiecom.de/lna3000.htm (in German)
The price is DM300,- (approx. $ 140,-)

I am wondering what type of GaAs FET they use....

Does anybody have some plans online or know of some application
notes online?

Thanks in advance,
/Marc

I had the VFO out of my 830 and did not have to remove the front panel.
I undid the screws for the counter unit and moved it aside a little.
The VFO itself comes out after removing the four screws from the
corners of the VFO that hold it into the front panel.

Cheers,

Brian

>experiencing?

I think the fact that the LED is out suggests a simpler problem - that the
radio thinks the external VFO is selected. Of course, if there is no
external VFO then it isn't going to work very well<grin>.

Is there some kind of jumper plug that's supposed to go into the external
VFO socket if you don't have the second VFO? Is it possible that jumper is
loose or missing? Also, there may have been a little switch fastened to the
inside of the external VFO socket used to connect & disconnect the internal
VFO; maybe that switch is flaky?

(I would think that dried grease would only stop the VFO at some frequencies
- that as you tuned across the band it would intermittently start and stop
working. But I don't have a whole lot of experience with the 830.)

Doug---

> I think the fact that the LED is out suggests a simpler problem - that
> the radio thinks the external VFO is selected.

I've checked both the schematic in the manual and the PC board layouts in the service manual, and the only thing I can come up with is S21, which is the external VFO control switch, but does not appear on any of the diagrams in the service manual.

A new development:

This morning, I decided to take some time to look about on the inside of the unit. I removed the top cover and powered the unit up. The display came on, VFO light lit, and everything. With the power remaining on, I then proceeded to replace the cover and reattach all the connections. It seemed to be working. This afternoon, again, it wasn't working. No display, no VFO indicator. Power off, I removed the cover and applied power. It worked.

I don't understand how this could be happening---it seems to me that it must be some sort of mechanical failure (cold solder, bad ground, etc.) on one or more of the boards. It could also be a PLL unlock, as the unit sends a blanking signal, taking out the numeric display, if the PLL unlocks---but what would taking off the cover do to rectify that?

Whatever it is, it's very intermittant and _VERY_ annoying.

Any ideas as to where I should start sticking probes? :)

Thanks,

Henry C. Gernhardt, III

Just having *some* output from the VFO is not good enough. The output
must
be in the proper frequency range and of enough amplitude, otherwise the
PLL looses lock and the display goes off.

The confirming point is if you have the VFO jumping freq, first a little
then getting worse and it gets better for a while if you spin the dial
lock to lock a few times. Eventually the only cure is cleaning and
greasing.

There are other *possible* causes but given the age of the radio and
design
this is both the most likely and the easiest to fix cause.

I have seen this in a TS-120, a couple of 130's and a couple of 830's.
On the TS-130 you can pull the VFO without even removing the top cover.

You might check all of the wires carefully. It might be a broken wire or
even a bad solder joint at one of the jacks on one of the pcb's.

If the display is on with the cover off, check to see if the frequency
changes smoothly as you turn the dial. If it is smooth then the grease
is likely *not* the problem.

I am cleaning out to get some room (duress) wife says they go.

1. Radio handbook 23rd edition Sams.
This is the latest one. Good shape, has a stamp from an address in
Malaysia. Has a binder crack the second from the last page. Current
price $35.
Sold.

2. "The big red book" Radiotron Desighers Handbook Fourth edition ,1498

pages Hard bound
Good shape only minor abrasions. I see this book sold for $100 to
$120 on ebay.
$80 plus shipping. Save $20 to $40.

3.Reference Data for Radio Engineers Fifth edition Sams for ITT 1968.
Hardbound
45 chapters covering it all.
$20 plus shipping.

4.Electronic Designers Handbook Landee Davis and Albrecht 1957
Hardbound
23 chapters of good stuff
$20 Plus shipping.

5.Microwave Measurements Ginzton Hardbound 494 pages 1957
11 chapters of knowlege
$20 plus shipping

6. Applied Electronic Communications Kellejian Hardbound 1982
Circuits systems Transmission 14 chapters
$20 plus shipping

7. Notes on the network ATT 1980 Soft bound
Network planning devision
$10 plus shipping

8. Radio and electronics handbook 2nd edition 1952
Hardbound Warn but all there 580 pages 4.5 X 7 in size
$10 plus shipping

9. Communication system engineering handbook Hamsher
1967 927 pages 548 illustrations Hardbound
$20 plus shipping

Shipping from 33428 zip

We now have the "Peanut Whistle Two" QRP CW transmitter with 7.040 MHz transmit crystals available. Many hams suggested that we carry the crystals for those of you who don't have any in your junk boxes. Just got another fresh shipmet in this morning. We are offering the xtals to you AT OUR COST with the purchase of our "Peanut Whistle Two" 40 meter QRP CW transmitters. These lil' units are a blast! ONLY $19.95 without crystal...ONLY $29.95 WITH crystal!! (Plus applicable shipping and handling...) BTW, if any of you are new to QRP, 7.040 MHz is the recognized international QRP calling frequency for 40 meters.

For a photo of the PEANUT WHISTLE TWO and further deatils, please visit:

Hello Paul,

I need to get one of those RSGB VHF/UHF manuals though. I saw one once
and was totally impressed. I have seen some of the old ARRL VHF manuals
from the tube era, too, which are awesome, as well.

I hope to put a circuit diagram on the web soon with my version of a
receiver front-end using a compactron with dual pentodes in just such a
circuit as you describe. I'll post the URL as soon as it is ready and
invite comments.

not so sure about the QQE02/5 or 03/20 design, my Yaesu FL-dx-500
transmitter had a 12AT7 mixer - not particularly good in any respects,
but whatever else circuit tested they had worse gain, so complete
reconstruction was the only way out of the problems.

The circuit converted 455kHz to 9MHz, but had bad may bad spuriouses,
and my solution was to use 9MHz SSB generator with XF9A xtal filter

What is about the best two-tone IM dynamic range of a tube mixer for HF??

I'm able to get only about 90 dB IMDR on a tetrode mixer, and about the same on a triode (6J6).

I'm cathode injecting a TV tuner RF amplifier type of sharp cutoff high transconductance tetrode with about 4 volts of injection. I've got a 500Hz BW MDS of -142dBm and the IM just comes out of the noise at -50dBm with 2kHz spacing.

I can sure do much worse, but I seem to reach a point at around 80dB IMDR where it is tough to get beyond unless I get really careful...even with tube type.

Are there any detailed reference books on old tube type mixer designs?? Are there any tricks like traps or special terminations???

I'd like to get up around 100dB IMDR without going to solid state mixers. If I have to convert to solid state, I might as well gut the receiver.

Squires in "A New Approach to Receiver Front-End Design", QST Sept 1963, used the 7360 as a first mixer. I believe this was the prototype for the Squires-Sanders receiver.

He didn't report two-tone IMD as that is a more recent metric. He performed cross modulation testing and claimed that with a 2uV desired signal and an undesired signal 14 KHz removed, that the onset of noticable interference was with the interfering signal at +94 dB. This was with a 2.5 KHz BW crystal filter. He claimed 112 dB at 100 KHz spacing.

I have this issue and if you want to see it, I can scan and email.

Thanks!

I'd like to see that article Wes, if you could scan it.

I sure don't have any 7360's, but I have other beam deflection tubes
used in color TV demodulators. I think 7260's are over $30 each nopw
and very rare!

Any idea what the best ole tube receivers did, other than those using
beam deflection tubes???

FYI, I am using the HP 54143 PHEMT. It is VERY friendly with respect
to noise matching and input reflection. I have a bag of 'em
since I had to get them in quantity -- if you look, they should be
available
for between $2 and $4 each. There are more inexpensive PHEMTs,
that might be better for other LF (<3GHz applications), but the HP
seemed
to have the best combo of input noise characteristics, input matching,
gain, and ease of bias (it requires positive gate bias, so it is
slightly
easier to deal with source inductance issues.) Actually, it seems to
work
best at <1GHz wideband apps if you use about .5nh to 1.0nh, in the
source lead, therefore providing a very nice input match to reasonable
input impedances. (The HP PHEMT has very large noise circles making
input noise match easy.)

If all you need is the 2.0dB NF range, you might want to look at the
Stanford Microdevices part number sga4586, but it is just SiGe bipolar.

Both the HP PHEMT and the Stanford Microdevices parts have high output power capabilities, and arent' very susceptable to overload.

Wes, I would also very much like a scanned copy of this article if you
get a chance. I've been studying up on hollow-state mixers for the last
few months and I am very interested in balanced mixer designs.

Hi Jim

I just couldn't resist responding!

I agree with almost everything you're saying--Interesting? Without a doubt! Fascinating? You bet! Unique? Wel-l-l-l-l...yes, but only if you're passing through...I have very little choice about where to go parts hunting...It's Akihabara or the Internet and it's been that way for 6 years. In some ways, however, component shopping is actually better than it was in Australia.

The only thing that made me laugh out loud was the image of anyone RUNNING anywhere! Radio center, Tokyo Radio Dept Store, New Akihabara Center, Rajio Kai-Kan? They're always packed with people and the aisles are 3-4 feet wide maximum...RUBBING is closer to the mark, IMHO! :->

Best wishes
Adam

Hello,

The following valves are for sale. They are unused unless otherwise specified, and mostly in original boxes. They are all in stock and can be shipped immediately to anywhere in the world.

2 pcs 3069M Large, round CRT in super heavy duty packing material each in a wooden barrel. One in

completely new, obviously never unpacked (only by me for inspection), the other one seems also to be new and unused but it has

been opened by someone. US$ 250.- each

8 pcs F16-10LD CRT by GEC (some boxes says 'Haltron' on the outside. I have not opened to verify). They

are obviously all unused. US$ 150.- each

1 pcs F16-10LD CRT as above, but made by Mullard. US$ 150.-

1 pcs F16-10LD CRT as above, but this one is used. It has a little spot on the screen. US$ 75.-

4 pcs 7BP7 CRT. The boxes says 'Haltron' I have not looked inside. Unused and unopened. US$ 100.- each

5 pcs 5FP7 CRT. The boxes says 'Haltron'. Some are opened and some are sealed. All the valves are

obviously unused US$ 75.- each

6 pcs P535/1E STC pulse modulator valve. Also coded CV 427. It is similar to 715C. All unused. US$ 50.- each

1 pcs P535/1E Same as above, but this one seems to be used. US$ 30.-

6 pcs C1148 EEV pulse modulator valve. Unused and in original boxes US$ 35.- each

12 pcs C1150/1 EEV pulse modulator valve. Unused and in original boxes US$ 38.- each

3 pcs C1166 EEV pulse modulator valve. Unused and in original boxes. US$ 40.- each

1 pcs QF 451 Ferranti. Looks like a radar TR switch and unused. US$ 20.-

1 pcs KS 9-40D Mullard klystron. Unused in sealed box US$ 20.-

4 pcs M509 EEV magnetron. Also coded CV 3982. Unused in
sealed box US$ 50.- each

2 pcs M599 EEV magnetron. Unused in sealed box US$ 50.- each

1 pcs JP 9-75 Mullard magnetron. Unused in sealed box US$ 50.-

7 pcs 24B1 STC trigatron valve. Unused in original box (Strange
looking valve) US$ 30.- each

11 pcs 725A Western Electric magnetron. Unused in sealed boxes.
US$ 30.- each

Best regards,

Henry,

This sounds to me like a classic "dry" solder joint. We have sold many of these units and I have come upon similar issues on two or three occasions. Once fixed they just run and run! Other Kenwood radios such as the TS930 and TS940 are also well known for this problem as are Yaesu rigs of similar vintage.

GL with the fix!

5039. Stability Equations...

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-25 22:22:40 UTC
From: "Peter Norgard, KI0EG" <BojangleChicken@yahoo.com>
Message-ID: <9m98fjbv1@dipsy.missouri.edu>
Source record: 50735

This is going to be relatively long.

According to Wes Hayward's "Intro to RF Design" [IRFD]:
For unconditional stability of a linearly operated device, the Rollet factor, K, must be greater than 1
K = (1 + |deltaS|^2 -|S11|^2 - |S22|^2)/(2|S12*S21|) > 1 =>
Unconditional Stability
deltaS = S11*S22 - S12*S21, which is just the determinant of the 2-port s-parameter matrix

I just picked up another RF design book in order to prepare for my senior capstone EE lab. The author, David Pozar, expresses some additional conditions for stability in "Microwave and RF Design of Wireless Systems" [MRFD]:
For unconditional stability of a linearly operated device, not only must the Rollet factor be greater than one, but also deltaS must be less than one, |S11| < 1 and |S22| < 1.

Why does MRFD list additional constraints? Is there any reason not to list the additional constraints, as in IRFD? Was there a change in the current thinking regarding stability calculations recently?

As of late 1997 all the restrictive spreading codes have been done
away with,
it is quite possible to use Any off the shelf wireless device
reclassifed
under Part 97. Part 97.311 specifically deals with amateur SS.
See my overview which covers all the issues of reclassifying these

cards:

High Speed Amateur Packet Radio Using Part 15 Wireless Cards:
http://www.qsl.net/kb9mwr/projects/wireless/plan.html

As for the ID requirement, thats not a problem just embed your
callsign in a
ping packet that is automatically sent every 10 mins. (Also covered
in my
link above)

>Yes, these things are wonderful and getting cheaper. Will they
replace
>terrestrial microwave?, not likely. However, they do have a lot of
>excellent possibilities for both amateurs and non-amateurs. I could
easily
>see, with some coordinated effort, these devices being used to create
a
>regional area wireless network backbone, something akin to packet
(only lots
>better), no small effort there, but possible.

Bingo! Theey are cheap and I have a cost comparision on my page
comparing a
modified part15 set up to a conventional packet setup, guess which one
is
cheaper? We know which one is faster.

>
>The speeds are getting up there too. 10Mbps is available today,
which

>Regards,
>Bob-KA9FLX
>mailto:ka9flx@arrl.net
>http://www.qsl.net/ka9flx

I personally feel this is the future for amateur packet radio or it
should be. And TAPR's development of their 900 MHz frequency hopping
SS radio also suggest this.

5041. Re: Solarcon IMAX 2000 low on received mod

Hi
The IMAX 2000 is a dc grounded antenna. So on somw frequencies it appears as a short circuit to the reciever. To listen on the lower bands, unscrew the coax connector at the rig and slide it back so only the center pin is connected.

Sounds like you are there full time, while I have only been there a
few months at a time for the past 20 years. Most of my trips to
Akihabara were to buy parts to fix the equipment I was sent over to
work on, so we just need caps, transistors, ICs, etc.

>The only thing that made me laugh out loud was the image of anyone RUNNING
>anywhere! Radio center, Tokyo Radio Dept Store, New Akihabara Center, Rajio

Since I was working, I would often end up there on weekdays. I suspect
you were there on Sat. It's a lot easier to get around at 11AM
thrusday morning. But, you bet, I've been there when it is crammed,
too. ;-)

Unfortunatly, that was a former job and I'm unlikely to ever get back
there. Great memories. I miss it.

Where are you living there?

and 'dry solder joint' often use to be a particular joint where a
particular component often had to be be installed late in the mounting
process...., any idea about such cases?

Remember an early Standard C158 (?) had this particular problem, an RF
choke in audiofilter after clipper wasn't soldered in one end. Usually
almost impossible to trace unless you had been told where to look

once found a commercial version with transmission line through some
ferrite beads, worked above 1GHz. Does somebody have more information?
Believe it was a balanced, but low z transmission line

Tried to copy it, but wasn't particularly successful

> process...., any idea about such cases?

If you happen to know where to look, that would be wonderful. As it stands, I turned the unit on yesterday, and it seemed to be working perfectly. Same today. I will eventually want to send it in to have the VOX circuit fixed, but for now, I would like to keep it here as it is my _ONLY_ HF rig.

BTW: Any ideas on the VOX circuit? It simply doesn't work---no QSK, no sidetone, no VOX, no matter the setting of the VOX gain control (which is also the VOX switch, assuming VOX is on).

Thanks,

Henry C. Gernhardt, III

Hello.
I bought recently a velleman kit (K1771).
It's a fm oscillator. I assembled it, and turned it on, but it doesn't send any signal. Do I have to do something else or just connect everything to it's places marked on the board?

Excuse my bad english...

Hello,

PC 900 is a B7G base triode with a heater of 3.9V 0.3A, u=76 and a gm
of 14.5mA/V
A very promising valve to experiment with in low-level stages, both
audio and HF/VHF amplification. It was developed for use in VHF and
UHF television tuners.
I have 400 pcs in stock and the price is only $ 3.00 each or $ 1.50
each if you buy 100 pcs or more. The valves are NOS, in mint
condition, original boxes and the label is Haltron, but they are
rebranded, and I think the are originally made by Philips or Siemens.
E-mail me if interested.

Best regards,

Arnold Goksyr

DEMOSTENES - N6899 Balestrand, Norway
Tlf. +47 5769 1340 Fax +47 5769 1267
http://www.demostenes.no

Thousands of different valves in stock as well as
sockets,transformers,books and components.

Hi Jim

I'm living in [Oh-Mi-Gosh!] SAITAMA--Tokyo people know it as a huge, remote prefecture, famous for farming and mountains. I'm actually only one local-train-stop out of "greater Tokyo", tho, and have to transfer once to get to Akihabara, less than 30min away. My days off are Mon and Tue, so that's when I spend most of my time there. 11:00am on any day would be fine, I'll bet, as it's only an hour after the usual Tokyo "opening time". I can only go there in the afternoons. It's always packed, then!

I know that I'd miss it, too, if I had to leave.

Cheers
Adam

5050. Re: Stability Equations...

<BojangleChicken@yahoo.com> wrote:

|This is going to be relatively long.
|
|According to Wes Hayward's "Intro to RF Design" [IRFD]:
|For unconditional stability of a linearly operated device, the Rollet
|factor, K, must be greater than 1
| K = (1 + |deltaS|^2 -|S11|^2 - |S22|^2)/(2|S12*S21|) > 1 =>
|Unconditional Stability
| deltaS = S11*S22 - S12*S21, which is just the determinant of the 2-port
|s-parameter matrix
|
|I just picked up another RF design book in order to prepare for my senior
|capstone EE lab. The author, David Pozar, expresses some additional
|conditions for stability in "Microwave and RF Design of Wireless Systems"
|[MRFD]:
|For unconditional stability of a linearly operated device, not only must the
|Rollet factor be greater than one, but also deltaS must be less than one,
||S11| < 1 and |S22| < 1.
|
|Why does MRFD list additional constraints? Is there any reason not to list
|the additional constraints, as in IRFD? Was there a change in the current
|thinking regarding stability calculations recently?

G. Gonzalez in "Microwave Transistor Amplifiers", 1984, Prentice-Hall, p99 says
all conditions (K > 1, |delta| < 1, |S11| < 1 and |S22| < 1) are required for
unconditional stability.

That's what I was looking for, I think. I do not understand why the magnitude of the determinant must be less than one, though. The other two conditions, (|S11| and |S22| both < 1) seems to make some sense to me, assuming my way of thinking about it is correct. I guess all of this means I just have to read deeper and actually work at deriving some of the equations.

Thanks

It appears netscape is not monitoring their web server nor
reading their email as it has been down for at least 4 days
for the second time in two weeks.

If you can't get to

jttp://sites.netscape.net/kd9jq/hamradio/kd9jq.html

then try;

http://user.mc.net/~kd9jq/hamradio/kd9jq.html

If this lack of response to their web server continues
I may have to move it to the mirror permanently.

For those not familiar with my web site I provide
ham radio homebrewing resources and info, along
with some freeware design programs.

I will answer technical questions on what I'm experienced
with or help direct you to a site if not listed.

Source record: 50651

I recently acquired a Hewlett-Packard Model 455A Probe T Connector, which permits the measurement of RF voltages on 50 ohm coaxial lines using the RF probe on the HP 410B&C instruments. With it came an HP 46A-95C. It's a nickel-plated plug which slides perfectly into the probe port of the 455A, and has a type N female on the outside end. The plug end appears to be filled with an epoxy potting material, with a small spring pin protruding from the center. There's a straight through connection between the pin and the center of the N connector, and it measures 75 ohms between the center pin and the outside. It appears to be made to work with the 455A, but just how remains a mystery. Could anyone shed any light on this curious gadget? Thanks.

I too, am in the repair business and do not take lightly the ethics of repair. They had the equipment for almost a year and never even opened it up. They never responded to my requests for an update or sent me any kind of communications regarding the status of its repair. If you or I ever ran our business that way we would not be able to enjoy our good reputations. Don

Here are the rules you must accept in any service industry:

Never make excuses. The truth is the only answer that is ever acceptable.

The customer may not always be right, but you must treat him as if he is.

Respect and courtesy for your customers, workers, and suppliers are
absolutely essential.

Never over-promise. If it's going to take a year, say so.

Never under-estimate. If it's going to take a grand to fix it, say so.

If you're so busy that you can't attend to the details of customer service,
then you can't afford not to hire somebody who will take on that task.

If you point your finger at a customer and say 'He's the problem!' then
note that while one finger's pointing at him, the rest are pointing back
at you.

An argument occurs at the intersection of two jerks. You can avoid
the argument by behaving in a non-jerk-like manner.

Deliver the unit as promised. If you can't get to it in the quoted time,
contact the customer and explain. If he asks for it back, return it
without hesitation, with an apology, and postage paid. It's worth it
for good customer relations.

Your standard of service must be the same for all customers.
Do EVERY job to the highest standards and EVERY customer
will be pleased and will deal with you again.

Last but not least, NEVER jump customer's equipment in line.
They come in first, they get serviced first. No customer's equipment
should ever be set aside to do an expedited repair on another unit
for a more important customer. No customer is any more or less
important than any other because they're all paying you.

CJ

The ARRL Antenna Book shows how to make "shortened dipoles" for limited space. I built a 1/2 size antenna for 160M. It worked, but efficiency wasn't too good...plus I had it only about 10 feet off the ground ;) Probably the two worst effects of running shortened antennas is lower efficiency and narrower bandwidth. The 160 I descirbed had a 2:1 SWR bandwidth of about 12 KHz, so as you can see, tuning it was pretty critical (and I thought having it so close to the ground would widen the bandwidth...HA!)

Good luck, I'm sure you'll find something workable.

To my knowledge they all subscribe to a service provided by Global
Atmospherics in Tucson. Global's website on
http://www.glatmos.com/nldn/nldn.html provides a bit of an explanation of
how it works, though they don't say exactly what frequencies are monitored.
The data is delivered to the local stations by satellite.

The ARRL publishes a couple of books on microwave design that covers
microstrip construction.

I've always found 'Akiba' the best place on earth to access any type of electronic component - but the specialist vendors who handle only one or two component types form a small but proud community of old-style tradesmen and you must demonstrate that you understand all the technical background concepts in Japanese before they will take you seriously. If you can manage this then they open up and always go to great lengths to find just about anything you need. You may discover they had more technical knowledge than you suspected from first impressions.

Whatever criticisms you may have - this is a far cry from Radio Shack or Maplin where the sales assistants have difficulty understanding the general category of component that you are looking for as opposed to the electrical characteristics of one specific device versus another within the smaller subfamily.

Just in case any readers are in Tokyo on business this coming weekend - the largest hamfest of the year will be held in the Pacifico Yokohama Exhibition Stadium over Aug 31 to Sept 02. This event typically attracts over 40,000 visitors (multiple-count) over the 3 days and there is always a large volume of old unwanted measurement/analytical equipment and silent key sell-offs.

If you want the best junk then get there before me !!

Correct. Most of or possibly even all of the problems with
DC receivers can be solved by building a phasing method RX
and using elaborate filters or DSP filtering. This would
make the receiver a lot more complicated than a simple
DC RX. This approach might be viable if you just build
the RX front-end and use a computer with stereo sound
input to do the DSP filtering.

Good screening is important with DC receivers - however, if
yours ain't broke, don't fix it.

13dB of carrier suppression is pretty poor. I'm sure you could easily
get more than 25 or 30dB with a simple two diode modulator.

I get pretty good results with this circuit:

5073. 17 mtr DSB - finishing up

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-27 21:58:56 UTC
From: n2cqr@clix.pt
Message-ID: <3b8ac245.1078617@news.clix.pt>
Source record: 50668

Poor band conditions on 17 allowed me to put down the microphone and work on the rig.

Recognzing the inherent shortcomings in the receiver that consists of only 4 transistors and 4 diodes (other than the VX0), I decided to build a switching arrangement that would permit me to go to an external receiver (my trusty Drake 2-B) with the flip of a front panel switch. I used a 3PDT switch and a small relay, and a second switch (to turn on the VXO for spotting). The circuitry works very well -- when the DC receiver can no longer handle the QRM, or when the weaker signals get lost in all the noise that is getting through the relatively wide passband of the DC RX, I just throw the INT/EXT RX switch, turn on the VXO, quickly zero beat the 2-B and I'm in business. (Of course, the Drake 2-B died just as I completed the INT/EXT circuit! Thank God I had a spare rectifier tube in the junk box.)

Here's a question for the groups: Am I right in thinking that when the going gets rough (QRN, QRM) the simple DC receiver will simply not be able to compete with a good superhet like the 2-B? I think the passband (and the noise) will always be about double that of the superhet, correct?

Another RX question: I see guys soing to great lengths to shield their DC RX VFOs. I built mine in a PC board box, but I haven't gone to the trouble of bringing in the DC leads through decoupling caps. In fact, I haven't even put the cover on the box yet. The RX seems to be working fine. Any sense in going to a lot of effort to button this thing up?

As for my AF amp problems, after many failed attempts to add additional AF amplification, I came across an article in QQ that discussed the big differences in sensitivity among HI-Z headphones. This prompted me to reach into the junk box and experiment. I found a set of old military headphnes that were significantly more sensitive than those that I'd been using. So I no longer have a need for more amlification. (I'd given up on the idea of having a speaker in the cabinet. If I want to listen on a speaker I can just switch to the 2-B.) With the high sensitivity phones, I needed to turn down the AF gain -- so I put a 10k pot between the output of the 100 db pot and the headphones. (I didn't want to invite feedback by putting the long leads at the input to the AMP.)

My problem with the overload of the AF amps by mixer products beyond the audible range seems to have been reduced significantly by turning back the RF gain to minimal levels. Jake, N4UY, is sending me some

88mh toroids. I'll try these in the diplexer circuit to see if some additional low pass AF filterng will help.

Here's a TX question: Why did Doug Demaw use a balanced modulator with only 2 diodes? Wouldn't he have gotten better carrier surpression with a 4 diode arrangment? Could it been that it wouldn't have had much effect on the signal? (My carrier surpression doesn't seem to be that great -- I can see about 250 mw of carrier when I push the PTT down. Output PEP is probably 5-8 watts.)

I put the rig in an old Bud cabinet and used the bottom of a cake pan as the front panel. I think it looks pretty good. Pictures on my web site.

Let's not forget that a direct conversion receiver usually has
very little front-end selectivity. If someone worked on that,
the results might be quite different. Back about 1969 or so,
one guy wrote a number of articles for CQ on direct conversion SSB
transceivers. Unique was that he was using crystal filters right
on the signal frequency. Not too useful if you want to tune
the band, but other than that, a fairly "perfect" receiver. No
problems with conversions, yet the antenna fed right into the
crystal filter (or was there a simple amplifier first?). After
all, the superheterodyne is not an end in itself, but merely a means
of getting narrow selectivity without problems tuning the band.

I've never seen the article, but someone once had an article in
CQ about front-end crystal filters. His intention was to remedy
problems from strong local signals, such as when contesting. But
one could go mid-way between a single-signal filter the inability
to tune the band, and a broader filter that didn't pass only one
signal but did allow limited tuning.

Of course the common direction now is to build mixers that won't
easily overload, so the front end filtering is less necessary,
and then you only have to deal with single-signal selectivity.

He may have used a two-diode balanced modulator because he was
trying to show variety. Four-diode mixers have become fairly common,
so perhaps he wanted to show something different. If you look
at older SSB transmitters, two-diodes were pretty common. Remember,
those books were not collections of construction articles, but

"notebooks" and the circuit used may not be the ultimate choice. Are you getting a real null with the trimpot? The circuit may not be well balanced. One thing you'd often see in old circuits was a trimmer capacitor somewhere in the balanced modulator, in addition to or instead of the trimpot.

Michael: Yea, I have four diodes in the RX detector. I suspect that
DD was shooting for simplicity here. Two diodes are also used in the
ZL2BMI DC transceivers.

I am definitely getting the null with the trimpot. I suspect that my
less than stellar carrier rejection comes from less than totally
symetrical construction and less than optimal shielding. One of these
days I'll go in there and see if I can improve things.

BTW, in SSD there is a neat "two way" four diode mixer circuit for use
in a transceiver. I might try that with the next rig.

Thanks, 73 Bill CU2JL

5083. Catacomb Band-Switching

Newsgroup: rec.radio.amateur.homebrew

Source record: 50680

Hi,

March 2002 of the CQ 'Radio Classics Calendar' features the still-born Millen DFP501 receiver which, so it states there, used 'Catacomb Band-Switching'. A web search cast up the information that this was some kind of moving coil-rack, akin to a linear turret tuner. Unfortunately it didn't explain the 'catacomb' part of the description unless it simply means that the coils were in individually screened cavities.

Can anyone enlighten me on this and further, what exactly did the 'tune' button on the front of the Millen rx do as I believe that on some National receivers the tuning knob engaged with the coil rack and I would have expected the same here.

5088. Hilbert filter binaural reception

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-28 12:37:40 UTC
From: Leon Heller <leon_heller@hotmail.com>
Message-ID: <9mgkurchp1@uranium.btinternet.com>
Source record: 50691

I've just implemented a Hilbert filter on my Analog Devices Ezkit Lite DSP system, to generate I and Q binaural outputs from the audio output from an Rx. I want to experiment with DSP modulation and demodulation, and this looked like a good starting point. I used the macros available from Rutgers University to simplify the code:

http://www.ece.rutgers.edu/ftp/sjo/ezkitl/ezkitl.html

It's the standard arrangement, with a delay in the In-phase path. The filter has 127 taps, and was designed with the new FilterExpress filter design software available free from Systolix:

http://www.systolix.co.uk

This software is excellent, and can design and simulate all the FIR and IIR filters you are likely to want.

The filter seems to add a lot more 'presence' to the signal, and makes it easier to pick weak signals out of the noise. The filter can be switched in and out with the user interrupt button; the FL1 LED is on when the filter is active.

Please email me if you would like the source code. The latest Timewave DSP has a similar option available. I think they charge for it, though.

I want to solder a bridge from point A to point B on a handheld device. It's a simple job that will increase its receiving capacities, and doing it myself will spare me all of the hassles associated with approaching FCC boot lickers who wouldn't do it anyway.

Problem is, it's a very tight area and I'm a novice. I realize inaccuracy is the kiss of death, so what I need are tips from you seasoned veterans on which type of solder and solder gear I should use, and the correct method of ensuring that I get it where I want it!

Thanks in advance. Is there any doubt we're living in a police state?

Aircraft often have similar receivers. They're sold under the name
Stormscope (BF Goodrich Aviation) or StrikeFinder (Insight). These
receivers actually DF each lightning strike with a pair of orthogonal
LF loop antennas (very similar to an ADF setup).

There are a whole slew of patents on this issue. However the bottom
line is this: you can tell the range of a lightning strike by
examining the attenuation vs. frequency of a crash of static. The
more energy you get at higher frequencies, the closer the lightning
strike is.

This effect works right out to 100 miles away. You can show strikes
beyond that distance with degraded distance accuracy. This is called
the "radial spread" phenomenon.

These devices are commonly used by general aviation pilots. The
advantage to a storm scope is that you don't need a big antenna to
make it work. Pilots use this sort of scope for *avoiding*
thunderstorms. The theory is that wherever you see lightning there is
probably some serious convective activity nearby. As long as you
avoid a cluster of strikes by 25 miles or more, you should be ok. It
is a useful tool for navigating around a thunderstorm (not through
one).

However, these tools are NOT what the weather broadcasters use. They
simply record a strike and the precise time it came in (within
micro-seconds). Given three or more stations where a strike was
heard, it then becomes possible to triangulate the strike and even the
polarity. This is done by computer. It is a more brute force
approach, and it is not portable.

Get a soldering pencil with a very small tip on it. The wattage should be around 40 watts. Find some solder that is 60% tin and 40% lead, this is usually called 60/40. There are several differant mixes of tin to lead but 60/40 (tin is usually the first number) is the best unless you hapen to locate some 63/37. Also should have a ROSIN core flux. DO NOT use the ACID kind. The flux is a material that keeps the oxygen in the air from messing up the joint. If the gap is very large you can use a piece of small wire to help fill in the gap. If the connection is copper and not already coated with the shiney tin colloring you may need to very lightly polish or scratch the copper tuil it is bright and shinney instead of the dull red. The dull red copper is oxidised and will not take the solder very well if at all. Heat the joint if possiable and then feed the solder to it. YOu might want to put a very samll ammount on the tip of the pencil and use it as a help to transfer the heat of the tip to the joint. Do not try to put a bunch of solder on the tip and transfer it to the joint. Get the pencil good and hot so it melts the solder, the put a small ammount on the tip just before going to the connection. Thenwipe it off with a clean rag. You can wet a sponge and wipe the hot tip on it to get it clean just before the connection.

YOu should find some old equipment even if you have to go to the Good will store and buy a cheap transistor radio to practice on. YOu may have an old computer board laying around to practice on. If you do not have very good eye sight you may wnat to get some of the maginifying glasses. Guess that I should put in some of the standard saftey stuff such as wear some kind of eye protection and the drops of solder will be very hot so don't drop any on you. It melts around 370 deg F depending on the exect percentage of tin and lead.

i have a transfomer thats to big for what i need
would like to trade for a little smaller transfomer
when i say too big, i mean sec voltage wise

mine is 220 pri with a 4000 and 5000 tap on the sec
@ 1 amp wt is 62 pds its 8x8 and10 tall like new cond

id like something around 220 pri with a 2500 to 3000 sec tap
at .750 to 1 amp

i might sell outright too but rather trade

Hi,

I have just added a great article on 'Miniature Magnetic Loop Antennas' by By David Posthuma, WD8PUO, to the Elecraft web page. Dave has done a great job describing his experiments and results with these antennas. The article includes pictures and diagrams of his designs.

You can find Dave's article in our Elecraft monthly 'Tech Notes' section at:
http://www.elecraft.com
There are links to this section on the left and right side of our main page.
(Look for the small loop antenna picture on the right.)

I have several more great articles to format and post to the page too. (On transverter interfacing, RX filter optimization etc.) Stay tuned..

I have a 444 with all dead PA transistors. I looked at 429's sometime back but put this project on back burner. I suppose that you can get matched 429's from RF parts.

TT told me years ago that the 444 had a nasty habit of losing the transistors and they never really isolated the cause. The guy I talked to said they suspected either parasitic's or probably in many cases serious overdrive.

They said that they took a number of them back for refund. What about FET's in place of BJT's?

Hello,

PC 900 is a B7G base triode with a heater of 3.9V 0.3A, u=76 and a gm
of 14.5mA/V
A very promising valve to experiment with in low-level stages, both
audio and HF/VHF amplification. It was developed for use in VHF and
UHF television tuners.
I have 400 pcs in stock and the price is only $ 3.00 each or $ 1.50
each if you buy 100 pcs or more. The valves are NOS, in mint
condition, original boxes and the label is Haltron, but they are
rebranded, and I think the are originally made by Philips or Siemens.
E-mail me if interested.

Best regards,

Arnold Goks

>What is exactly a homebrew radio?

You take a bunch of electronic components, a couple pounds of dark malt,
5gal of water, yeast nutrient, hops, and brewers yeast. Mix up the malt
extract with hot water, toss in the hops, let it cool, add the nutrient and
the yeast, and let it ferment for a while. Once it's bottled and aged
properly, you give it and the parts to somebody with more electronics
knowledge than sanity, and ask them to make you a radio.

I have not worked with this enough so I don't know if it will work for your application but the eagle layout is great for hobby use. It is free for a limited version, no number of holes restriction but it limits you to a 3.8" x 3.8" board (or something like that). PCBexpress likes the eagle editor as well. I don't have thier website URL on hand but a quick search on google should get it for you

Henry,

The only advice I can give is to thoroughly check over each circuit that has failed using a magnifying glass to check for these dry solder joints. They are notoriously difficult to locate any other way.

GL!!

Mark

Anybody know anything about the cells used in most of the current Dell and Compaq battery packs? I've got a few bad packs laying around that I've been meaning to crack open to see if any of the cells will still take a charge, and if they'd be usable as a part of a solar-charged QRP rig.

I'm looking at a Compaq PN 135214-002 14.8V 3.2Ah pack right now. What are the odds, given that it the laptop doesn't like it anymore, that it's worth trying to salvage any of the guts? I don't seem to have a Dell one handy at the moment, but they're from the Latitude CPi series, mostly.

Anybody happen to know the pinouts on these, so I can test them before cracking them open?

5113. Kam HostMaster problem

I have been running the DOS version of Hostmaster on a 486/33 computer under Win95 with my Kam TNC. All was well.

Just picked up a Pentium/200 computer and it won't run under Win98. If I go to a real DOS prompt, it runs just fine, so the software is OK. There must be something about the speed or Win98 that HostMaster doesn't like.

Anyone have any suggestions (other than get a new program ;-( )?

Thanks and 73,

Henry WA0GOZ

Here's the quick and easy way to do a modification like you want.
Get what is known in the industry as a "solder pot". Large commercial
companies use them for quick, efficient soldering.

For a small job like yours, turn the heat control all the way up.
Faster is better, as any expert solderer will tell you, and more heat =
faster soldering. If you can get the solder to boil, so much the
better.

After removing the plastic parts of the scanner you wish to modify,
carefully dip the entire circuit board in the solder pot. Not only will
this establish the connection you want, it will resolder all existing
connections, and some you didn't even know you had!

At this point, the circuit board will be larger than before due to added
solder, so take the plastic parts and dip them into the pot at this
time. Pull them out of the solder pot and, using bare hands, quickly
mold them around your circuit board.

Since you now have a "hot" modification, you will want maximum receive
power from your radio. Discard the batteries and make a direct
connection to the 120 VAC outlet, avoiding the use of fuses. Fuses
cause a small but measurable power drop and are a waste of money anyway.

Before plugging in for the first time, call 911 but just let the
receiver lay on the table. Your neighbors will appreciate this. With a
little luck, you will be able to hear the actual 911 response on your
newly modified radio!

Is this a great hobby or what? :-)

I'm building an old DC rcvr from a design I found in ARRL manual circa 1981. I have all the parts, I think, but would really appreciate a slug tuned adjustable inductor coil, with a nominal inductance of 4.5uH. ARRL lists it as a JW Miller 42A476CBI or its equivalent. It combined with a 10pF air adjustable will form the heart of the VFO. I would pay whatever we agree as a fair price.
Contact me direct please.
Thanks!
Tom

5116. Syntor information

Hello All,

I have recently acquired a UHF Motorola Syntor complete with the secure voice option. From the internet I have determined that it is a 50 Watt unit with the receive preamp option and it is capabile of being modified to operate on 438 MHz. This particular model is not common in Australia, and so far I have not been able to get hold of a circuit diagram or very much in the way of modification info.

Can anyone out there help me with some info please ? I get the impression that these transceivers are popular with US amateurs.

What I need is :

Info on adapting it to take an eprom instead of a fusible link prom.

Info on the data structure in the prom.

Tune up details, eg meter test points, layout of the various filters, PA tune up info.

Remote head cabling, particularly how to remove the secure voice option and associated control unit. On my unit this looks very much like an afterthought !

A full circuit diagram !

Thanks in advance,
Colin Coles, VK2XCT.

> under Win95 with my Kam TNC. All was well.

Is HostMaster a terminal program or a BBS program? Since you have an external TNC, there isn't any reason not to continue using your old 486 as a dedicated packet machine, especially since your new(er) machine doesn't seem to like the software. Otherwise, if you want to multitask with your Pentium, I would look at new software. Sorry.

Hope it helps,

Henry C. Gernhardt, III

Go with the Electronic Workbench EDA. You can design and model the circuit and go straight to a board. It is fantastic, the learning curve is a lot simpler than Protel and others. I struggled from package to package because the steep learning curve. Now i use Electronics workbench and do boards with my hands tied behind my back.

Hi Henry,

I run Hostmaster under Win98 on a 500 MHz machine for both my KAM and KPC-3 just fine. I created icons on my desktop for both devices, open normal window, and close on exit. Make sure, in icon properties, that the working directory points to where you have Hostmaster saved. The exe files needs to know where the cfg files are. When I click on an icon it opens the programs in a DOS screen and closes it when I quit.

Sounds like maybe you need some minor adjustment to your PIF file (icon)????

Again, I agree very largely with the writer--I've found those places, too. [The "few exceptions" that I referred to previously]. Those are the places where the people staffing the shops and stalls are the SAME 1 or 2 individuals on every return visit. The places where, with the merest glance at one's shopping list, they politely inquire: "Hamu rajio?" and are full of good advice.

In the other places they can look at the same list in great detail and without a flicker of recognition--there's no indication that they could tell an RF transistor from an interesting insect--simply declare that they don't have anything on the list. It would be unnecessarily embarrassing to try to engage this kind of person in a polite rap about Shockley and Bell Labs or even about the invention of ferrite...

On the entire rest of the planet, where business is more important than "mystique", even if you were crass enough to ask for BC108s, you'd not go away empty-handed, if the salesperson knew SOMETHING about electronics and transistors, IMHO.

BTW, I am speaking as a 6-year resident who does at least a few trips, sometimes six trips a month, to Akihabara. First impressions? Well, that's ONE way of putting it, but really...!

Best wishes
Adam

I have been modeling a class A tuned amplifier at about 7MHZ in SPICE. Using AC Analysis, the output runs pretty close to the expected gain (37db). It shows a very nice peak at the design frequency of the high Q tank circuit (7.68 MHZ). I have a large value parallel resistance across the coil.

When I run the Transient Analysis however the gain is about 20db less. I was careful to run the analysis at the peak frequency indicated by the AC Analysis and just to be sure ran it at several frequencies above and below that point.

Just for grins I modeled an untuned class A amp designed for 20db gain and it looked good under both AC and Transient analysis.

Can anyone tell me what I might be doing wrong or at least which analysis I can believe?

TIA

Did you run the simulation long enough to let the LC tank circuit(s) to reach their steady state values? The time required can be estimated from the "Q" of the tank circuit. Normally the time would be figured to be equal to the period of one cycle of the resonate frequency of the tank times the tank circuit "Q" at a minimum. If you ran the simulation for a length of time only equal to one or two cycles of RF then the tank circuit has not pumped up to it's steady state value yet. I run in to this problem all the time simulating resonate power supply circuits where I work.

Source record: 50626

The AC analysis assumes a very small signal, and that the circuit has been running long enough to reach steady state. So if you see a difference between the transient and AC analyses, one or both of these conditions isn't met in the transient analysis. To test for the first, substantially decrease your input signal amplitude and see if the output decreases a like amount. If not, the input signal is big enough to cause nonlinear operation somewhere in the circuit. To test for the second, run a much longer analysis and see if the output signal amplitude is still increasing at the end of the run. You might also check the DC biases and make sure they're the same for the two analyses.

Hope this isn't too dumb sounding, but are you sure the program you are using will allow you to include device Q into the simulation? I know that the OrCad spice program (evaluation version) that I use doesn't let me do that (unless I am totally missing something). However, Harmonica from Ansoft does allow this.

In a recent article J.B. Hall wrote:

> Can anyone tell me what I might be doing wrong or at least which
> analysis I can believe?

The small signal analysis first linearises the circuit, then calculates the gain from that. Spice will happily predict a 70 volt rms output from a class A amplifier running off a 9 volt supply. (or even millions if you tell it the input voltage is thousands ;-) You can use the predictions to determine voltage gains, frequency responses. Actual values? Yes, but you gotta take care.

The transient analysis doesn't linearise the circuit, so its predictions are closer to the real world values. (Spice transient analysis "knows" when the transistor hits saturation or cut-off.)

Yes; was in RS one day, assistant answered phone nearby and clearly didn't understand what was being asked for! Overhearing only one side of the conversation, I, at one point I spelled out "M I C R O F A R A D" for the hapless individual who had apparently written down "FARD". Then he came over and asked the guy serving he counter whether they had 1) a diode 2) a 68K resistor and 3) whatever that 'Fard' value was (I think he lost the "MICRO" part of it!)
"Sorry we don't carry those!" Anyway to give him his due it was probably his first hour on the job!
Cheers.

May be the ferrite mix wasn't the right one for the frequency?.

There is two return loss bridge types, built with only transformers and a load or with also resistors. The last has 3 dB more insertion loss, but should work for an extended frequency range.

I've built both types but didn't made any meassurement with them (almost still never used them either), just with HP commercial ones that wasn't allowed to look into.

There is a text book design in QST sept 97 p.34-37 from N6JF and a basic analysis in "Intro to Radio Frequency Design" p.152 from W7ZOI. Both are the resistor type. The balun transformer type simply replaces the input divider arm with an balun splitter. The only one I've found recently with some other niceties is at:

I have scrounged up a big quantity of .1 uF Polyester/Metal Film caps. These, according to the databook, are equal to ceramic disk caps in all uses. These are NOT NPO caps. Made by S+M Components.

How about 50 for $3 or 100 for $5.00 500 for $20.00 (they're abt 15 cents each from Mouser) I ship in a 4 by 7 padded envelope.

These are .1 uF, 10%, rated at 250v - New Stock, on paper tape, nice long leads. Good for bypass caps I am told. That's what I have used them for.

I still have NEW BNC chassis connectors for

25 for $12.40
50 for $21.00
100 for $36.00

I also have:

LM7808CT voltage regulators. TO220 case. 5 for $4.50
LM7812T voltage regulators. TO220 case. 5 for $4.50

22uF 35v electrolytics - $6.00 for 100 (if you need larger or smaller qty, email me)
These caps are on paper tape, NOS (New, but old stock) made by Richey.

2N2222's in METAL TO18 case - 25 for $7.50

Let me know if you're interested. All prices are post paid to the USA.

Thanks - My address on QRZ is good.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3B8EF444.955F6D50@eznec.com>
Source record: 50634

The Q of devices is determined by the resistances and inductances or capacitances you've specified, along with the frequency. It's not generally specified as a separate variable in SPICE. Q is often not a very useful parameter for a transient analysis, since many different frequencies, and correspondingly different Qs, can be present at once. When you're doing a transient analysis with sinusoidal drive, the concept of Q can be useful in predicting and interpreting what's happening, but you still don't specify it as a separate parameter -- it's determined by and inherent in the component Rs and Xs.

If you want super simple, how about a resistor and an analog meter movement? Otherwise, Radio Shack used to publish their "Engineer's Notebook" series of books and they had a circuit using 1 IC that converts an input voltage to outputs to drive an LED array.

Down here in oz, there was a construction project (kit) for one in our
Electronics Australia mag in Dec '81. Dunno if that mag eversaw light
in your libraries ....

Ditto Electronics Today International, had a Peak/average LED level
meter in Jun 81, and a LED peak program meter in Oct 83.

Don't have any of these mags/articles, just chased them up in the
project index for each.

May help ...

Source record: 50644

Thanks everyone for the ideas. I am still struggling though. Here is what I have done relative to the main points that were suggested:

1. Transient analysis may be too short, not allowing me to observe the steady state conditions:
I ran the transient analysys for as much as 1ms but it seemed to reach steady state in less than 10us. The circuit is resonant at 7.68Mhz. and the Q is about 180 (3.36uh with Rp=29500).

2. Circuit is overdriven or operating in a non-linear fashion:
I was running the input at 10mv so I tried 1mv and 100uv. The same gain was observed at these three input levels, about 19db. Even with 37db gain as indicated by the AC Analysis, a 10mv signal should produce a 700mv peak signal on the collector.

DC bias conditions for each type of analysis were also in question. I need to study that a little further and see what I can determine. Meanwhile I'm still confused.
Thanks again for the assistance. 73

The probe itself isn't too difficult. What is difficult is getting the special cable, it isn't ordinary co-ax, but made from some sort of resistive compound.

I've found LED displays to be very hard to read outside in sunlight --
particularly when running at low current to conserve batteries --, so
the analog meter idea might be a better choice. I do recommend that you
do a little experimenting outside before putting too much effort into
it.

Hello All,

Rap 'n' Tap is at:

http://www.midnightscience.com/rapntap/forum.asp?forum_id=3&forum_title=Crystal+Set+Clubhouse

The thread is called: 'Experimenting a long time ago'

The 145 & 179 ohms refered to above are the head phones DC resistances, not the impedances. My work arounds, posted in 'Experimenting a long time ago,' kludge the receiver to accept higher & lower DC resistance phones. The receiver appears to have a regen(?) mode and hops from very low volume to much higher than any of my other 1-transistor receivers. However, I have to throw in internal battery resistance, Miller capacitance, &/or interwinding capacitancece to to see any possible positive feedback path. Any assistance in removing the kludge & understanding the detector's operation would be most welcome.

Unfortunately, some side threads where accidently started. Hopefully, we won't have to search them to missing information.

Young-Min,

The miniature audio output transformer I used in replicating your radio is a Radio Shack 273-1380.

Steven

I've also found the LED bargraphs don't really have enough resolution when
you're trying to "peak something up". Only ten segments, unless you want to
cascade two ICs. The analog meter probably is the best bet for this
application.

Any thoughts on this scheme for a homebrew hf receiver.

50 MHz lpf
passive mixer
300 MHz dds lo
70 MHz if (using maybe sat tv technology) include some agc control
here to make up the 130 dB probably needed overall ...
ad9870 rated to 88dB on spec .. might be able to pick some more up
in the dsp at the end
70 Mhz ?saw filter/xtal filter/lc tanks
ad9870 if
10.7 Mhz 2nd if using 10.7 Mhz crystal filter
digi output to ad21065 devl. kit
..
2nd stage ... use the 300MHz dds as transmitter
.
4 bpfs on the front end to do 0-50 50-100 100-150 150-200 MHz
.
why has it not already been done?

cheers
Stephen
zl1any

ps anyone with easy access to ad .. would you be able to help me
obtain samples of the relervant chips .. I can pay reasonable
amount .. but can't go to the moq!

> I have been modeling a class A tuned amplifier at about 7MHZ in SPICE.
> Using AC Analysis, the output runs pretty close to the expected gain
> (37db).
> When I run the Transient Analysis however the gain is about 20db less.

Well I think I have found the problem. I have been using a SPICE program that was supplied by a semiconductor manufacturer and intended as a design aid for switching regulator design work. Well, for lack of a better approach I downloaded the demo version of Electronics Workbench and ran this circuit on it. It looked much better, and after fine tuning the input voltage and length of simulation as suggested, the results agreed perfectly between the AC and Tran analysis.

Now back to the original SPICE program to try and find the problem. I took the tank circuit out and fed it with a voltage source at the resonant frequency. In series with the source was a 30K resistor (the value I specified for the inductor Rparallel). The AC analysis was just as you would expect with a peak of 0.5*Vin at the resonant frequency. The Transient analysis however was much lower. I removed the inductor Rp entirely and the output came up to about 0.13*Vin. That would indicate an effective Rp of 4.46K so I changed the resistor in series with the source to that value and sure enough the output was 0.5*Vin.

Once again my thriftiness cost me untold hours of pain. Even though my freebee SPICE program was described as: " …the Spice is fully functional and allows other types of circuits to be simulated in a user-friendly environment….”, it seems that a resonant circuit was not one of those "other types".

Thanks again to everyone who suggested solutions.

This may be your answer. The chips are interesting, but they
not always straightforward to obtain.

Also, high-speed mixed-signal design can be a nightmare to
get right...

Hello All,

Well, I accidently posted this to a new thread. Here's trying again:

Rap 'n' Tap is at:

http://www.midnightscience.com/rapntap/forum.asp?forum_id=3&forum_title=Crystal+Set+Clubhouse

The Rap 'n' Tap thread is called: 'Experimenting a long time ago'

The 145 & 179 ohms refered to above are the head phones DC resistances, not the impedances. My work arounds, posted in 'Experimenting a long time ago,' kludge the receiver to accept higher & lower DC resistance phones. The receiver appears to have a regen(?) mode and hops from very low volume to much higher than any of my other 1-transistor receivers. However, I have to throw in internal battery resistance, Miller capacitance, &/or interwinding capacitancece to see any possible positive feedback path. Any assistance in removing the kludge & understanding the detector's operation would be most welcome.

Unfortunately, some side threads where accidently started. Hopefully, we won't have to search them to missing information.

Young-Min,

The miniature audio output transformer I used in replicating your radio is a Radio Shack 273-1380.

I came across some parts in the basement that I've had around for years and don't even know where I got them or what they are.

Eimac X578U ? They appear new and it says Electron Tube on the tags. They appear to be some kind of microwave tubes. Heavy little suckers, for their size. I have maybe 6 of them.

Are these possibly worth anything if I sell them?

I have a great working Tektronix 547 50 MHz oscilloscope with a lovely assortment of plugins. I have dual trace, four trace, calibrated offset, and spectrum analyzer plugins plus a few spares. I also have some manuals but not sure what they cover.

The second unit needs a capacitor. It's an old Dumont 401R, about 100 kHz bandwidth, complete with manual. It only needs the resonating capacitor for the self regulating power transformer, I believe 0.84 microfarads or so at a few hundred volts. The tubes alone in this baby make it worth its weight (which is considerable) in parts.

The third unit is a fine working Tektronix 316 portable unit (well, the carrying handle is broken). This one is good to 5 MHz and has the usual Tektronix quality and performance. No manual.

I'd rather not ship these. I am in the Los Angeles area. All reasonable offers considered.

I don't think that I would use a 70MHz 1st I.F. when using the a DDS that is clocked at only 300MHz. The "sweet spot" for a DDS that is clocked at this frequency would be in the 40 to 80MHz range. If you would be tuning the receive range of 0 to 30MHz, a 45MHz I.F. would work out better. I know that Analog Devices says that you can go up to 40% of their clock frequency, and you can, but when you get up in this range, the artifacts in the DDS output increase in amplitude. Now, if they were all out of band where they could be filtered, that would be fine, but you get some pretty "good" ones that are in band, and when your desired output signal mixes with one of these things, it gets pretty interesting. I have been using the AD9851 in my own receiver designs, and it works out ok. I am band-passing the DDS output, amplifying the output, and low-passing the amplified signal, with good results.
Now, as far as you question about this not having been done before.....Rockwell-Collins did this over 4 years ago, with the 95S-1 receiver. They didn't sell too many of them, at 7000 or so dollars each. I did get to play with one of these receivers when I was working at Rockwell-Collins, and it did work fairly well.

Hi Stephen,

Sounds like a fun project.

A couple of comments. In no particular order.

The DDS will clock fast, but you will probably want to stay at < 0.26 times the clock frequency. The problem can be looked at as the harmonics of your output being sampled back down to be in band. For example in the vicinity of 0.48 times the clock frequency you get a pretty darn big spur at 0.52 times the clock. At some point the filter to take this stuff out gets so complex that it's just not worth building.

The second DDS issue you will run into is that yes the spurs are > 80 or so db down, but there are a *lot* of them. The problem with this is that they start to behave like phase noise rather than like spurs. In other words you are dealing with hundreds or thousands spurs in a typical IF bandwidth mixing with input signals rather than two or three doing the mixing. The net result is that the dynamic range of the system is reduced considerably.

One way around this is to run a octave band VCO as your local oscillator and lock it to the DDS output. This can help clean up the DDS spurs, but it adds to the complexity of the radio. You also get a new set of spurs to deal with but at least they are at discrete frequencies.

Saw filters are very neat parts. They also are fairly broad or fairly high loss or both. This isn't necessarily a bad thing and there are ways around their limitations. They probably are not the best choice for a first filter in an HF radio though unless you are trying to do a "whole band at a time" type of radio. They should be a fine idea above 30 MHz.

Most of this (at least through the second IF) has been done before. It's not to uncommon to see high end wide band scanners done pretty much this way. You usually see older DDS chips in them though. They also seem to use some pretty high first IF's. It can be very hard to take care of 70 MHz IF feed through on a radio that covers 70 MHz and has a 70 MHz first IF.

The DSP IF processing is fairly new and fairly expensive. You will find that kind of thing in the higher end military gear or in cell phone base stations. It's not as common in commercial or VHF ham stuff.

Can't help much with the samples. I've found AD to be fairly easy to work with though. You might try giving the local office a call and see what they can do for you. A year ago they probably would have been a bit hard to convince. I suspect that in today's market you would have a good chance at getting some parts.

About the only other major issue that you will run into is PC board layout. The pitch on the leads on these packages is *tiny*. Doing the good old flip the chip over and wire it dead bug style is a major pain on these parts. I have yet to fine a way to do this stuff reliably without doing a PC board.

Enjoy!

Bob Camp

I finished mine yesterday. I've never built a regenerative or DC
receiver before, so I can't compare it. However, I've found it to be
quite sensisitive. I can clearly hear a 1.0 uV signal on the signal
generator, and for 2 transistors and an audio amp, that isn't bad!.

Stability is quite decent. You can easily listen to SSB and not have
to keep chasing the knob.

I do find a small amount of frequency pulling with the antenna
attenuator. A KHz or so.

The audio sounds very clean and the regeneration control is smooth. No
strange sounds; just regenerates or not.

It took me about 12 hours, including metal working and electrical
work.

I'd use 40/60 solder (the first number is lead, second tin) and a 240
watt soldering gun.

Melt the solder on the tip and let it drip on the board for the best
connection. Scrape off the excess with a dremel tool.

Another perspective:

I have dealt with Mr. Knowles and his companies for the last 16 years on a fairly regular basis. I have always found them to be responsive, competent, and responsible. Hopefully, whatever went wrong was the exception rather than the rule.

Just my opinion.....

NOW AVAILABLE, Program "LINOSITE.exe

This simple program covers the bare essentials of radio propagation between antennas which are within straight line sight of each other. Refraction due to the atmosphere and ground reflections are ignored.

Antenna gains are inputted relative to an isotrope. For given path distance and transmitter power output, computed results include field strength in vicinity of receiving antenna, receiver power input, receiver input volts, S-meter reading relative to 50 picowatts.

For better appreciation of performance of VHF and UHF beam antennas the beam-widths in degrees and equivalent square apertures are also computed.

Approximations for other paths can be obtained. Earth - satellite links ?

Download from website below in a few seconds. One file = 35 kilobytes. Not zipped up. Run immediately.

I did notice the spurs that Bob is talking about, and they do manifest themselves the way phase noise will. When I was living one block away from KMRY, in Cedar Rapids, Iowa, I would notice a rise in the noise floor of the receiver when I would get within 200KHz of that station. Using the same receiver strip with a PLL type of synthesizer, the problem was not noted. I had toyed with the idea of using a DDS as a tunable reference oscillator in a conventional PLL circuit. Maybe one of these days.....

It would be very good if amateurs in Mannheim, Germany to check this system out and document the lack of interference! I suspect the ending statement is not correct, since I can hear computers using twisted wire networking for over a mile away!

How are they getting away with that with CE regulations, or are they not enforced for German goods sold and used in Germany???

I came across some parts in the basement that I've had around for years and don't even know where I got them or what they are.

Eimac X578U ? They appear new and it says Electron Tube on the tags. They appear to be some kind of microwave tubes. Heavy little suckers, for their size. I have maybe 6 of them.

Are these possibly worth anything if I sell them?

Tom:

You'r correct. There is little or no "balance" in that electric wiring and
it goes
everywhere. As you mentioned, it's surprising that the EU allows this since
their CISPR regs, equivalent to our Part 15, are much tougher than in
America!

Deutche amateur radio associations better get on this case fast. Using
power wires for signalling at high frequencies is bad for us radio folks.

This Power Line Transmission system (PLT) will be disastrous for HF hams
especially with overhead powerlines in the area. I believe that in the UK
PLT has been dropped ,same in a number of other countries. PLT would wipe
out HF comms.

5196. Impedance of speaker

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-03 16:53:52 UTC
From: swampthing <swampthing@lpws.zzn.com>
Message-ID: <9n0cpk$1eb$1@plutonium.btinternet.com>
Source record: 50592

A mate has asked me to mod an extension speaker for his short-wave radio.
It says on the radio extension speaker socket
that the output impedance speaker has to be in the range 8 ohm to 16 ohm.
The speaker he want's to use is a 4 ohm...
Can I just put a 4 ohm resistor in series to make it 8 ohms?
Is an impedance ohm, different to a resistance ohm?
Will it be best to just buy an 8 ohm speaker and put it in the cabinet?
Thanks for any help. Bob

Source record: 50594

If you add a 4 Ohm resistor in series with the new speaker the volume will be reduced a few decibels. Otherwise no problem. If it's not loud enough, go get an 8 Ohm unit.

5198. 'Choke Input' B+ Power Supply?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-03 17:19:07 UTC
From: Terry <tsanford@nf.sympatico.ca>
Message-ID: <3B93BB8B.229BF1B4@nf.sympatico.ca>
Source record: 50595

Choke input implies that there is NO capacitor on the output of the rectifier; right?
The cathode of the rectifier typically goes to a smoothing choke and then large capacitors provide 'smoothing' on the other side of the choke, perhaps with other stages of smoothing and decoupling etc. This is all in the B+ line at voltage above chassis.

My question is this.

In the case of choke input can the choke be in the 'negative' line? In other words one end of the choke would be connected to the centre tap of the power transformer (in a typical full wave duo-diode rectifier circuit) and the other end, typically to say the chassis or negative rail.

I believe some old 'field coil' loudspeakers were connected this way? To lessen the voltage to chassis/negative etc.

Comments, criticisms, questions invited. TIA

Terry.

BOB: Stick a four ohm resistor in series with it and should work fine.
Just put it in one of the leads.
Also you can think of it this way. It's a bit simplified but this is
pratical.
Half of the power will go to the speaker and be turned into sound. The
other half will be 'wasted' in the resistor.
The half power of the power that, as it were, will be wasted, will mean
a sound difference of three decibels. Usually referred to as 3 dB. The
human ear can barely detect three dB. even under the most perfect of
conditions; in fact you probaly have to turn down a radio by something
of the order of six (6) to twelve (12) dB to even notice the difference.
So the four ohm resistor will not be noticeable, but the whole set up
will be correctly matched to radio at a total of 8 ohms.
By the way I can send you a four ohm resistor, free, if you email me
your address. It will be a ceramic bobbin a little smaller than a
spool/reel of thread/cotton that is about one inch diam. and slightly
more than one inch long with a mounting hole through the middle and two
solder tags. Very easy to mount and wire.
Problem is; if it's in a standard envelope and the Postal Service put it
through one of their machines it will probably break (their machine that
is!).
Email if you wish.
Terry. Eastern Canada.

Terry:

Yes, you can place the filter choke between the center tap and ground...the ARRL handbook used to refer to this as negative lead filtering. (They may still, but I didn't check to see).

Another advantage is that you can use a choke with a lower working voltage rating since it is operating near ground potential, rather than at the B+ level.

From: "Bob Lewis (AA4PB)" <rlewis@staffnet.com>
Message-ID: <tp7ncobjj3ml16@corp.supernews.com>
Source record: 50500

Impedance is the measure of resistance to the flow of AC current. It includes not only the resistance, but also capacitive and inductive reactance, both of which vary with frequency. In a speaker you have primarily inductive reactance and resistance. The rating of the speaker (4 ohms) is only 4 ohms average or at some specified frequency and actually varies from several times that value to perhaps half that at some frequencies.

For a typical low output power short-wave radio you can probably just connect the 4 ohm speaker without causing any problems (a 1000 watt amp would be another story). If the radio can't handle the 4 ohm load, the first thing you would notice is clipping and distortion at high volume levels. You are not likely to damage the speaker or the radio.

I wouldn't put ANYTHING in series. The output impedance of most audio amplifiers is usually a fraction of an ohm (ie it's a voltage source). A 4 ohm speaker will be twice as 'powerful' as an 8 ohm, so you will have to set the volume a bit lower. There is a slight danger that you could warm up the audio output stage a bit if you use high volume, and the distortion might be a little higher, but I doubt if you would do any harm or notice any difference. However, if this speaker is operating in parallel with an internal 8 or 16 ohm speaker, it will probably sound louder than the internal speaker (ie it will tend to steal most of the power).

Regarding the 'impedance' ohm and the 'resistance' ohm, the purpose of a loudspeaker is to transfer electrical energy into changes of air pressure. When it is doing this efficiently, the AC electrical input impedance to the speaker should look mainly like a resistance. However, because the voice coil is an inductor, there is also some inductive component. Incidently, I believe that you can get a good idea of the AC impedance by measuring the DC resistance, but this is mainly a coincidence (it almost certainly depends greatly on the power-handling of the speaker).

The choke can just as easy be done in the B- line, it is there to "regulate"
the current/voltage, mostly used in old AM transmitters, where that kind of
regulation is needed.
Not needed in SSB amps, since the regulation comes from the caps used.
Using a choke type PS allows you to use less capacitence, than one without a
choke, for the same level of regulation.

Terry <tsanford@nf.sympatico.ca>
shared these priceless pearls of wisdom:

->Half of the power will go to the speaker and be turned into sound. The
->other half will be 'wasted' in the resistor.
->The half power of the power that, as it were, will be wasted, will mean
->a sound difference of three decibels. Usually referred to as 3 dB.

Nope. Sorry. If the audio output is a hard voltage source (and another poster noted this, to which I agree) and you put two equal resistors across them, the power relative to a single one of these resistors across the same voltage source will be one-quarter. This is due to the equal split of voltage across the resistors, which the way I teach it to my freshman and sophomore classes is 6 dB, which you will also note is a power reduction of one-quarter. Something about E *squared* over R.

Message-ID: <3b943045.7655650@news.clear.net.nz>
Source record: 50509

Hi
I have a Racal-Dana 9103 absorption power meter, 1 MHz - 1 GHz. One end has an N-type female connector, flange mounted to the heatsink of a 50 ohm dummy load. At the other end is a meter calibrated in 1-100 w and 0-25 w ranges.

The centre pin of the N connector has retreated into the connector body, and no longer mates with the male pin on connecting cable. Has any one had a similar problem?

Can someone please give me some advice on how to dismantle the unit to enable me to repair/replace the connector. I don't want to damage the unit or dismantle any more than I have to.

Hi, Terry. Yep, the choke in the negative lead is as common as not in
1930s sets.

> I believe some old 'field coil' loudspeakers were connected this way? To

Solid state directly coupled outputs often (but not always) appear as
"hard voltage sources", but certainly not always by any means!!

Transformer coupled (and especially tube-type or push-pull transistor
outputs) often behave more like a combination of current and voltage
limited sources.

It is not a cut and dry issue because the design of the audio stage
has a lot to do with how it appears at the output terminals.

If the audio stage in this receiver was a "hard" voltage source (what
we might consider for our purposes an infinite current but voltage
limited source), they likely would not be specifying an 8 ohm minimum
impedance. It very well might be current limiting, not available
voltage, that is setting the available power rating into a defined
impedance.

What I try to teach people is to not leap to conclusions without
knowing all the facts.In this case, we can make no assumtions without
doing a load pull on the audio output or looking at the output system.

Contrary to what some might think, all systems are not voltage
limited. I hate it when I hire people and have to re-educate them.

>Thanks for any help. Bob

Bob, More than likely you are OK using a 4 ohm speaker, but be careful
to check for anything unusual like heating of the audio output device
or distortion.

There are several issues involved that are being overlooked, and no
one can give you an absolute answer because none of us know what radio
you have and how it is designed.

Some designs can be unstable when terminated in an excessively low or
high impedances. Some can damage the output device from excessive
current or heat when terminated in a lower-than-design impedance. But
as a GENERAL rule the design should have enough headroom to use a four
ohm load without any noticable problems.

However, your best bet (and the safest bet no matter what anyone says)
is to follow the guidelines the radio manufacturer gives you. Whoever
wrote that warning knows far more about that particular radio than any
of us do. hell, I don't even know what brand it is, or if it is tubes
or transistors!

If you do what they say, and the radio has a problem, it won't wind up
falling on your shoulders. None of us have to face your friend even if
it isn't our fault, so it is best to do what the instructions say so
you can always say "I did exactly what the radio designer told me to
do".

>rail.

Yes. In this case the center tap of the transformer will have some AC
voltage with respect to the chassis. That isn't a problem in
vuirtually all transformers, although I'm sure there might be an
exception somewhere waiting to nail someone.

There also is an issue of transients if the field would suddenly
collapse in the choke, the load become shorted, or during power up.
There are cases whene the peak voltage can get rather high, but they
are rare.

The choke must have a certain critical inductance for the MINIMUM load
current to be drawn, or regulation will be horrid! Regulation, if you
add a choke without meeting critical inductance, can be many times
worse than a capacitor input supply. You also MUST select a choke that
is NOT series resonant with the filter capacitor value. That series
resonance should be lower in frequency than the no-load inductance of
the choke.

The choke will vary in inductance with load current, unless it
includes a substantial air gap or flux capacity of the core is large
compared to the flux at maximum operating load.

Most chokes are designed with a minimally sized core and an air gap so
they do not saturate too soon.

Overall you are better off with a capacitor input supply unless you
have tube rectifiers or are concerned about power factor on the power
lines.

>I believe some old 'field coil' loudspeakers were connected this way? To
>lessen the voltage to chassis/negative etc.

Yes they were. They often had a hum-bucking system to prevent the AC
modulated flux change from introducing hum into the speaker.

Choke input supplies were popular with vacuum tubes, because tubes
have a very limited ratio of peak to average current. That is why you
see them in old gear (not because the old gear is AM gear).

With semiconductors, the ratio of peak to average current can be very high without ill effect. That is why you don't often see choke input supplies in modern gear (not because it is SSB).

2w8ji@contesting.com (Tom W8JI)
shared these priceless pearls of wisdom:

->Solid state directly coupled outputs often (but not always) appear as
->"hard voltage sources", but certainly not always by any means!!

I hate to pop your bubble, but in 99% of the stuff that has been produced for the mass market since 1970 the stiffness of the source relative to 4 or 8 ohms is quite high...certainly enough for a first approximation of a 6 dB loss.

->
->Transformer coupled (and especially tube-type or push-pull transistor
->outputs) often behave more like a combination of current and voltage
->limited sources.

Oh, come on. Except for a rare audiophile who thinks tubes have a softer sound (which they in fact do) you haven't seen a transformer coupled output in years in consumer goods.

->
->It is not a cut and dry issue because the design of the audio stage
->has a lot to do with how it appears at the output terminals.

You do this stuff for a living, sir? I do. We were trying to answer a generic question as best we could with the information available. Surely we could have asked the fellow (who wasn't skilled enough to figure out if he could put a series resistor to boop the impedance up) whether his output was totem pole, OTL, or one of a dozen other configurations. I doubt we would have gotten any more information had we done so.

->
->If the audio stage in this receiver was a "hard" voltage source (what
->we might consider for our purposes an infinite current but voltage
->limited source), they likely would not be specifying an 8 ohm minimum
->impedance. It very well might be current limiting, not available
->voltage, that is setting the available power rating into a defined
->impedance.

No sir, that doesn't happen to be the limiting factor in modern design for impedance limitations. P(diss) is the normal limiting factor, not current and not voltage. If you had read one of the other answers, you would have seen that he was advised to use a 4 ohm speaker and not run the audio output control to the wall, thus limiting the power dissipation. Excellent advice, IMNSHO.

->
->What I try to teach people is to not leap to conclusions without
->knowing all the facts.In this case, we can make no assumtions without

->doing a load pull on the audio output or looking at the output system.

Oh, right. We're going to ask some poor guy who just wanted to know whether to go to Rat Shack and buy another $10 speaker to do a load pull test on the output. What I try to teach people is to take the information given and make a reasonable answer in a reasonable time.

->
->Contrary to what some might think, all systems are not voltage
->limited. I hate it when I hire people and have to re-educate them.

I hate it when I hire people whose education has been screwed up by the likes of you and have to train them to think for themselves.

That may be true. I stated that, so you aren't "popping my bubble".

But factually, neither you nor I have any idea what the design of that
receiver is. All we know is the manufacturer did not want a load less
than 8 ohms on the speaker port.

Unlike you, I am not clairvoyant. If I don't know what the system
actually is, I simply say so.

It isn't painful for me to say "it depends" when I don't have all the
facts.

Tom's as-usual detailed discussion reminded me of my high-school days when I worked in a radio shop for my Elmer, W5QN. A common radio to come in the shop in those days was a particular Philco model that not only used the speaker field coil as the filter choke but went further to parallel-resonate it to 120 Hz with a capacitor. When that cap opened up, you could really hear the difference in hum level. Because that was a fairly uncommon practice even in those days, a lot of those sets played for years with hum because few repairmen either knew to check the speaker "tuning" cap or understood what it was for.

The world has come a long way - thank Heavens! <:}

Hi,
There is one advantage with putting a resistor in series
with the speaker. You will reduce the noise generated by the
LF amplifier also. Many (cheap) radios have LF amplifiers
that are uncomfortable to listen to at low volumes, due to the noise from
the LF amplifier.

The downside is that you will get a lower maximum volume.

==========
Just connect the 4 ohm speaker. You won't notice the difference.
It's probably 8 ohms anyway.

Thanks for the reply everyone.
I seem to caused quite a stir with my question.
The radio in question is a Realistic DX200 Short-wave set .
Its getting on a bit early 1980's I believe.
To tell the truth, I don't know where he got the 8 ohms from,
it don't say it on the back. He must have seen it in the hand book?
I have put a 4 ohm resistor in the speaker line and it seems ok.
I have told the owner not to turn it up to loud.
He is wanting to use one of those cheap
(not amplified) computer speakers.
I have put the resistor in and I cant tell the
difference in sound with an modified 8 ohm
and the original 4 ohm.
What a fuss. Thanks for the help.

Better still use a Resonant Choke supply, which eliminates all the problems Tom talks about. Designing a Resonant Choke supply seems to be a black art with very few people familiar with the technique. There is very little documented technical design details. For amplifiers they cant be beat, especially if you cant get 3 phase.

The Norwegian FCC-equivalent (www.npt.no) made a series of measurements
early this year, and concluded (not surprisingly) that the unwanted
emissions were far higher than allowed.

The conclusion was that the operators will have to reduce the level of
emissions by 30-35dB (!). If this is not possible, operation of these
kinds of networks will be prohibited.

The news letter (Norwegian version, only):
http://www.npt.no/norsk/Nyheter/Elforsyningsnett.html

>Find some solder that is 60% tin and 40% lead, this
>>is usually called 60/40.

For those who are nit-picking perfectionists, the best solder is not 60/40, it is 63/37. The reason is that any alloy other than 63/37 has a melting temperature that is slightly different (believe it or not) from the freezing temperature. This can cause a poor joint if there is any movement or vibration while the solder transitions through this area. Also, 63/37 has the lowest melting point of all tin/lead alloys and thereby is the safest for the items being soldered.

For ham use, 60/40 is ok and will do the job, but it is not the "best".

PL-259 type coax connectors. Using less than ~250 watts is asking for
trouble, either at the time or later on.

PL-259's can be soldered with wattages as low as ~100, but it requires
leaving the iron on the connector for a longer time, with possible
damage to the coax itself.

>There are several issues involved that are being overlooked

One of the issues not mentioned so far is the damping factor. Any moving-coil speaker like you have will tend to "ring" like a bell when energized by a transient voltage spike which is common in any audio waveform. Normally, when connected to a "stiff" voltage source, the voltage source will clamp the moving coil by acting like a dead short and thereby preventing "ringing". By adding a resistor in series, you lose some of this damping factor.

For ham purposes the loss of damping may or may not be noticeable, but it will be present. If it were me, I'd just hook it up straight, keep the volume down and if it sounds ok, go with it.

Yes, but be aware that the capacitance between the winding and the core
will tend to bypass some of the choke effect IF the core is grounded.

Just the opposite happens in a conventional circuit; the capacitance
actually adds to the overall bypassing.

=======
Talking PL259 connectors , I prefer the PL259 model which has the same coax
gland as an N connector.
i.e. with a metal flanged coax braid insert and rubber compression sleeve.
A bit more expensive but so much more easy to fit onto 10mm (3/8 inch)
coax ,like RG-8 , RG-316 etc.
And no heat to be applied to the connector's body.
In the UK these PL259 connectors are available from 'Westlake' .
Perhaps someone can mention a source in the USA.

I've been using a 140 watt soldering gun for many years, needing only a few seconds contact with the fitting, to get a good electrical and physical bond. The trick is to first drill out the holes. A 5/32 bit is usually about right. This leaves a fresh metal surface to wet and room to get the tip into the hole which makes the solder flow onto the braid in a couple of seconds.

Point of information please.
I understand? that many transistor amplifiers 'don't like' too low an impedance load across their output?
If that is so, it would seem wrong to connect only four ohms (Yes I know it's a complex Z with inductance and reactance and all that!) across an output which specifically says it should be eight; for the sake of the amplifier or radio output stage. Distortion?
I know we are not dealing with high power so even if we short circuited the output I presume the transistor output stage in a typical piece of consumer electronics equipment is not going 'toes up'.
Is this all correct?
Terry.

A resonant choke still requires a bleeder because it does not have
infinite impedance (it is Q limited), although it certainly can
provide a large reduction in required bleeder current. We also have to
use the correct choke design in critical applications if load current
varies.

Resonant chokes on the input of a filtering system also generally
require the choke being slightly on the high side of resonance, not
exactly at resonance.

If you get the choke resonated below the ripple frequency, it can ring
under some load changes and really bounce the voltage up. I was almost
killed in the early 70's using a resonant choke because I got the
choke at or just below resonance at the ripple frequency in a 3.7 kV
supply.

I had a 4160 pole pig and a oil filled cap, and used a resonant choke
with bleeders . When I powered it up, it flashed the tubes over from
grid to anode!

When I disconnected the tubes, the blocking and bypass caps exploded.

I disconnected the PA and clipped a 25kV insulated meter lead and
meter to the supply, and stood back on a rubber HV mat and flipped the
panel switch on. There was a loud crack and the meter lead blew in two
and flew up out of the PS cabinet and attached itself to my wrist on
the hand holding the toggle switch on the panel.

I was two or three feet from that lead! Lucky I standing was on the
mat and was working with one hand, because I only got burns up to my
elbow. Last time I ever used a resonant choke in a HV supply!

I eventually did a LV test and found that when charging the choke
"rang" the HV up to almost ten times the applied voltage. Because I
was using large power factor correcting capacitors for utility
transmission lines, they had a very very high breakdown. So I figure

the caps charged up to maybe 30 or 40 kV on the transient.

I learned a lesson from that. Moving the choke to the high side of resonance stopped the problem.

I've formed the opinion that chokes, as a general rule, are bad news. There are cases where there is a specific need to use them, llike power factor or ripple reduction, but they can sure give weird transient response under changing loads.

The worst thing that's likely to happen if you connect a four ohm speaker to an output specified for eight ohms is that the amplifier might not be able to provide enough current to drive the speaker to full output volume. However, the impedance of a speaker actually varies with frequency, and they're loosely specified, so as others have pointed out, a "four ohm" speaker is likely to have about the same actual impedance as an "eight ohm" speaker. I agree with Reg's recommendation -- hook the speaker up and don't worry about it. It'll work just fine.

Hi Bill,

I don't understand, what book said that?

If you put a capacitor across an inductor, the inductive reactance
increases. So choking effectiveness increases.

The only time stray C across an inductor reduces reactance of an
inductor is when the capacitive reactance in ohms is less than half
the reactance of the inductor in ohms. Try it on paper and see.

That's why we can put a small non-polarized capacitor across a choke
and have hum reduction.

>Is this all correct?
>Terry.

Nearly all transistor amplifiers are a "voltage source". That means for a given input, they will produce a certain voltage output, regardless of the load, within their limitations. For example, if you have a 4 volt output with a speaker connected and you disconnect the speaker leaving no load at all, the output will still be 4 volts.

No amplifier is perfect in this respect so there will always be a small change from load to no load, but the better the amplifier, the less the change. This effect is accomplished by a combination of negative feedback and power handling capability.

This is why using a 4-ohm or 8-ohm speaker won't make a lot of difference. The 4-ohm will be a bit louder because it's being driven by the same voltage and therefore receives more current - IF the amplifier is capable of delivering more current. If it isn't, you will get distortion of the waveform peaks.

I'm also sure a 4 ohm speaker would probably work just , but since we
know so little the safest thing would be to follow the instructions.
Some early solid state stages were very sensitive to load impedance.

That way, if something screws up for whatever reason, no one can say
"you didn't follow the manual".

Turns out it was a 1980's solid-state radio by Radio Shack. I'm not
sure wher that places it in "modern" terms.

Your question prompted me to dig out an old handbook and do some more research. I made an error by stating that the capacitance of the choke's core to ground was the issue in negative-lead filtering. It was actually the capacitance of the power transformer's core to ground they were concerned about. My apologies.

In the 1959 ARRL handbook, the discussion is on page 227. Here is a partial quote:

"With this connection [negative-lead filtering] the capacitance of the transformer secondary to ground appears in parallel with the filter chokes, tending to bypass the chokes. However, this effect will be negligible in practical applications except where the output ripple must be reduced to a very low figure".

Sorry for the mixup.

I'm surprised they said that. That is absolutely incorrect Bill.

Any capacitance across an inductor, which would be the case here,
would increase the reactance (and choking ability) not decrease it!

That is why we parallel tune a choke with a capacitor to reduce
ripple. The same is true with a balun.

In the case of a transformer, the effect would be so small as to be
negligable because there just isn't that much capacitance there, but
even considering that the Handbook has the effect backwards. At times
I see similar misconceptions with RFI chokes and baluns.

While there are cases where the extra C can be so large the reactance
added in parallel with the inductance will reduce the series
impedance, most or much of the time it actually would help increase
the impedance!

1.) A 500 ohm XL inductor has an impedance of 500 ohms to AC.

2.) A 500 ohm XL inductor shunted by a 750 ohm Xc capacitance has an
impedance of 1500 ohms and looks inductive.

3.) A 500 ohm XL inductor shunted by only 250 ohms Xc still has -500
ohms of series reactance to the frequency in question.

4.) XL has to slightly exceed Xc before the sine of reactance
changes.

We don't lose series impedance until Xc is less than half of XL at
the frequency of the undesired signal. In many cases the sign of X
won't even matter, so obviously that is a misstatement.

It is a two terminal network so far as the rest of the system is
concened.

The reactance the rest of the system sees in series with the load
increases, that is why capacitors are sometimes placed across chokes
inrtentionally ...and why the most effective "chokes" are traps that
are somewhat equal amounts of parallel C and L!

With reasonable Q in components at every frequency below approximately
1.5 times the resonant frequency, impedance increases from the
addition of the capacitor, so choking increases.

Well, where an egress occures .... just fire up as much power as you can muster right on that frequency (assuming it is in an amateur band). Usually the system will also be susceptable to interference on that frequency. Digital modes would probably be best although SSB would be worth a try (depending upon where in the band the interference is occuring). Hey, 1.5 KW of CW at 40 or 50 WPM might work wonders too!.

Enjoy!

Imagine 1.0 volt across 1.0 ohm. The power is 1.0^2 / 1.0 = 1 watt

Imagine 1.0 volt across 2.0 ohm. The power is1.0^2 /2.0 =0.5 watt

The power ration is 10 log (0.5/1.0) = -3 dB

shared these priceless pearls of wisdom:

Bill --

You fell into the same trap that the original person that made this error fell prey to...

The question was how much power the speaker was going to lose by putting a resistor of equal value in series with it...

To use your example, for a 1 volt source and a 1 ohm speaker...

With only the source and the speaker, I agree... (E^2)/R gives you one watt. This then is the reference level that we use. 1 watt.

Now put another 1 ohm resistor in series with that original resistor. How much voltage is across the 1 ohm speaker resistor? Half a volt. How much power is dissipated in a 1 ohm resistor with half a volt across it? 0.25 watts.

The power ratio is 0.25:1, and 10 (log 0.25) is in fact 6 dB.

>
> The power ration is 10 log (0.5/1.0) = -3 dB

Except - the case under discussion is placing a resistor in series
with a load. So, while you're totally correct about the total energy
delivered, the amount of power delivered to the load is half of
half as much:

Imagine 1.0 volt across 1.0 ohm; the current is 1.0/1.0 = 1A. The
total power is 1V * 1A = 1W.

Imagine 1.0 volt across 2.0 ohms comprised of two 1.0 ohm resistors
in series; the current is 1.0/2.0 = .5A. The power delivered to each
resistor is .5A^2 * 1 = .25W.

10 * log10 (.25) = -6.02dB.

"Somewaht equal amounts of C and L!" i.e. equal amounts of Xc and Xl at
the frequency of the ripple you want to block/attenuate. Eh?
Like up to the point you have a paralell resonant circuit at, say, 120
Hertz in the B+ line?
Terry.

You'll find the specs for the traps in any number of ARRL Handbooks and Antenna Books...or do a Google search on the web. It depends on the desired frequency(s). The trap capacitor can be the tricky part, but you can make them out of a short length of coax if you are running 'barefoot' power.

You weren't very specific about the kind of stream you want to capture or even what OS/hardware you are running.

Assuming W9x, this might work...

Run Hyperterminal from Start/Accessories/Communications. Click File - New Connection. Give it a name like comport1 (you can't use com1, its reserved). In the dialog that opens; the box for Connect Using: pull down and select Direct to Com1 (or what you want). Click OK, in the next box set the speed, etc. When you say OK the main window is communicating with Com1. You can type outbound data and see anything that comes in.

Under the Transfer menu you can select Capture Text to save to a file. From the same menu you can later stop the capture. You can then edit the data saved in the capture file. If the format makes sense you can import it into Excel as csv or something similar.

Its messy but you probably already have all you need.

Get a copy of the book "Serial Port Complete" - included with the book is a floppy containing the dynamic link which you need to program the serial port under windows. You can save the data to a text file.

This question comes up quite frequently on the microsoft bulletin boards for Excel.

If you want to measure and graph in real time(and don't really need to perform statistical analysis or record data for perpetuity), there is a nice utility for the basic stamp called "Stamp Plot" -- look at www.selmaware.com the "lite" version is free. There is a newsgroup for Stamp Plot on www.groups.yahoo.com

5291. Problems with UHF oscillator that doesn't (using tubes)

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-06 21:47:57 UTC
From: William Rayer <noone@nospam.com>
Message-ID: <SbSI7.7531$235.524724@news6-win.server.ntlworld.com>
Source record: 50488

Dear Newsgroup

I'm trying to build a UHF oscillator using valves. (Eventually I want to use it for a convertor so I can listen on 400+ MHz. But I have to get a simple oscillator going first). I've tried two types of circuit.

1. I tried a twin triode (6J6) in a push pull type circuit, with a hairpin tuned circuit between the anodes and feedback from each anode to the opposite grid. This works about the best, I got to about 300MHz with enough power to light a 1/4w globe (1.25v 250 mA). Also I tried a 6939 (twin tetrode) which gave about the same power.

I tried to use a resonant line as a tuned circuit, this was cut 15cm long and should be 1/4 wavelength. This should oscillate on 60cm which is about 500MHz so why is it oscillating on 300? The resonant line does not want to be a resonant line for some reason. I had problems getting above about 300 or 400 MHz.

2. Next I tried a single triode in a colpitts circuit. This used the same resonant line between anode and grid. It uses the internal capacitance for feedback. I used UHF triodes, and tried the 6AF4A and 6AN4. The books say these go up to 900 MHz. But my 1/4 wave line still was not oscillating at the right frequency. I could get to about 400 again, but no higher. The single triode couldn't light the globe at all.

I'm using a tuned line for checking the frequencies. The 7pin tubes used a PTFE base, but I used a ceramic base for the 9pin. I used 14 swg enamelled Copper wire for the hairpin and resonant line.

Has anyone done experiments with these tubes/circuits?

All the best

Yes, they will, I'm here to tell you they work, I'm using them right now,
and have never had a failure, but, you should use more than one in paralell,
to carry the current, which is roughly 4 times the DC current.

Try setting it up for 148MHz operation, then triple the output using a
varactor or active tripler stage.

Dunno. Try spamming a few more groups, maybe they'll have an answer for
you over on alt.crossposting.nitwit.

Thank you every body for heads up on the issue. It is hard to be specific
what exactly I need.
It is easier to look up the options and deside. Actually it is a meter which
has a rs-232 output and
I am trying to find a use for it, for example to plot SWR .
Thanks again.

Source record: 50397

Sorry Evan, I don't buy it. I've got some of the common door knob cap
catalogs here, the common ones are not rated for rf service. A lot of
people get away with using the wrong type door knob caps in amplifiers.
When real current is drawn, they will quickly fail and blow up.

Check the rating on a classic 858 type cap...

You need to specify the caps with an rf rating your amplifier does not
exceed. Otherwise your asking for trouble.

Your style label is not specific, next time mention a model and brand and
we'll check the ratings.

cheers
skipp

Tinning iron, used for metal gutter work. Pointed chunk of copper stuck at the end of a metal rod. Use a propane torch to heat.

As a jeweler would say...

An alloy's melting point is always below that of its parent metals,
down to the eutectic point, the point at which the molten alloy
solidifies without passing through a plastic, semicrystalized
"slush" phase.

Hi Frank

Sorry I can't REALLY help, but there are FM IF amp / AF preamps known as "266P32801" and CMOS multiplexers known as "409-051-2801". The digits "2801" looked somehow the most 'significant' to me...These are the only 16-pin DIP packages I could find with that string. Don't know the manufacturers, though. Still, maybe you can find some way to work out what you've got "by elimination"...

Good luck
Adam

Hi Frank,

A little bit of information on what type of circuit the chip is used in would be helpful. From my experience, the 2801 is a darlington driver chip, now well out of production. It's expanded newer brothers the 2803 and 2804 are probably still sold by Jameco and they have a web site.

Jameco can probably help you with data sheets if you call them on the phone and sweet talk their technical support people while your placing an order for the 2803. Other retailers of the 2803 include HSC Electronics in the Northern, CA. stores.

cheers, hope that helps you out.

: Yes, they will, I'm here to tell you they work, I'm using them right now,
: and have never had a failure, but, you should use more than one in paralell,
: to carry the current, which is roughly 4 times the DC current.

Using two or more low current door knob caps to do the same job as one
proper type and value cap, tends to get more expensive.

Continous high value current at frequencies above 1Mhz will often blow
door knob caps into pieces. Low duty cycle Amateur amplifiers are not
the same. Why use two or more when the right "one" will do... It's best
to use the actual rf data sheet values for safe operation at higher power
levels.

cheers
skipp

I looked at the original posting again. He does not state his intended use for the caps.

The statement that some types of doorknob caps are not meant for RF service is true.

The ones I have here are rated for RF service and the spec sheet is available at
http://www.highenergycorp.com/download/ceramic3.pdf

I have used these in tuners that operate at over 5KW without any problem so I doubt the 1KW amatuer service application would strain them at all. However, if used in a poorly designed circuit, they can be destroyed at a much lower power level.)

Tubes are still the best/only way for real power at microwaves. TWAs, magnetrons, klystrons, and gyratrons are far better at their job than solid state gear is ever likely to be.

I tend to agree though, if the project is just a tunable converter, you are not likely to need 30-40 dBm of UHF unless you have some enormous signals to handle. Perhaps the original poster wants to use tubes for other than technical reasons.

Ideally for modern down converters, you'd build a very stable crystal oscillator at HF or maybe low VHF, and multiply up to where you want using varactors, MMICs, and filters suitable for the frequency of the stage. Then apply the resulting LO to a minicircuits mixer module, or something more exotic depending on the frequency.

For an ultra-quick hack you can build a harmonic mixer by applying a gross amount of LO drive to a microwave diode and load resistor soldered right across the middle of three RF plugs, you feed the LO in one plug, the antenna in another, and plug the receiver in after a LPF on the 3rd. It leaks all over the place and has unmentionable other problems, but it works.

I have had far more disc ceramic caps "blow-up", than any of my door-knobs.
But Then I do not use the 850/858 type ceramic door-knobs, which can fail,
and also absorb moisture.
I use epoxy encapsulated door-knobs, which I have tested well over 30mhz at
5-6 amps of RF and never had one fail.
"Door-knob" caps are routinely used on "broadcast" transmitters, and many,
many amatuer amps If they were that bad, why would they still be used
there?
Typical amatuer amp will need to handle 10amps of RF in the tank circuit,
and 2-4 door-knobs in paralell will easily pass it, and thensome.
Also, door-knobs are commonly available in 3kv or more, and 5kv is OK for
most amps.
I use 20-30kv type, for extra safety.
Score card; "other types of caps that failed, MANY.

Door-knobs, that fail on me, NONE.

Enuff said.

>are not likely to need 30-40 dBm of UHF unless you have some enormous
>signals to handle. Perhaps the original poster wants to use tubes for
>other than technical reasons.

I agree it's archaic using tubes. I just prefer circuits using them, they're easier to wire up, easier to understand and I like them when they glow, although technically they're (mostly) obsolete. My (real) job is a software developer, so I like going retro for a hobby.

The converter idea was a bit further down the track. Before doing that I wanted to get an oscillator working properly, that I could use as a signal generator or maybe a grid dip oscillator. But I still have problems getting any kind of output from the oscillator.

I'll be more specific and ask some questions:

1. Should I use PTFE tube bases, or is a ceramic base OK?

2. What should I use for insulating material for these frequencies (say 400 to 1000 MHz). Is ceramic OK? Perspex? Tufnol?

3. At the moment I use a 1/4 wavelength line as the tuned circuit, but the frequency of oscillation is not determined by the length of the line (it's quite a lot lower). How can this be?

4. Does my 1/4 wavelength line need to be in an screened container? At the moment I pointed it away from the tube base, so it's surrounded by air.

5. Some of the circuits use isolating capcaitors, eg between the anode and the tuned circuit. Is it OK if I use a silver mica capacitor with leads cut to about 5mm, soldered as close as I can get to the tube socket? Or is this type of construction going to introduce large

losses?

6. Shoud I screen the tubes, using the little cans you can get?

In answer to the question about using a tripler, I wanted to keep
the circuit as simple as possible. According to the RCA tube
manual a 6939 (QQV02/6) is good for about 5W output at 500 MHz,
so it should at least be able to light a 1/4 globe at this frequency!
Also the early ARRL books (1940 ish) have tube oscillators that
generate quite a few watts directly, but they use weird tubes
I've never heard of.

All the best

Don't forget to take into account the capacity of the tube and its socket. Also
the leads inside the tube. Ceramic sockets are OK but for really high
frequencies
don't use any socket. Don't run high power if you want frequency stability.

Hi,

I have posted this before but with only one response. I really enjoy fixing up old homebrew tube or solid state receivers and tube transmitters. I'm interseted in very simple or very complex homebrew rigs!

If you have one that you want to sell and open up some space at home, drop me an email at enigma_y_2000@yahoo and let me know what you have and what the price would be.

Thanks in advance,

Bob

Virtually all 500pF 20kV caps are poor at RF.

Most 5kV or 7.5kV 500pF caps are good, but not always.

What is usable in a BC transmitter at 1.6MHz and lower is not always
good at 30MHz.

The best and safest thing is to always check the manufacturer's data.

This issue of using a tube didn't particularly attract my attention.
But the idea of a tuneable oscillator at that frequency range sure
seemed archaic. It went back to the era of modulated oscillators
and superregen receivers for UHF work. People were moving away
from that sort of thing, to crystal oscillators and multiplier
chains, well before the big move to solid-state devices. Yes,
there may be uses for tuneable oscillators up there (and certainly
a lot of moving up in frequency has been scouted by such simple
equipment), but I sure can't see a tuneable oscillator running
at that sort of frequency being practical for average radio reception.

The original poster wasn't talking about a high-power transmitter.
He was talking about an oscillator, and a receive converter. Not
some high-power circuit that would need a TWT or a magnetron.

That's all well and good, but if you want circuits that work,
you might want to reconsider this position. My job title, BTW,
is "Senior Software Engineer", working with embedded systems
for wireless data. UHF, mostly, around 900 MHz.

If they're "easier to wire up, easier to understand", why are
you having so much trouble? The modern stuff just works.

Laura, you're right, but don't forget that modern technology
can really dress up the 'old stuff'. Perhaps the most amusing
example of this was the '73' article on converting a microwave
oven into a 2.4GHz ATV transmitter, complete with an FM modulator
and PLL frequency stabilizer.

It was so outrageous I almost had to build one..

;-)

As for those older power oscillators, sure, they're noisier than
hell close-in, but I would not be surprised if there are more than a
few solid-state QRP-ish transmitters out there that are easily as
bad.

Perhaps it's just my jaded perspective - as much high-fallutin' code
as I've written over the years, I'm tickled pink to tinker with my
son's Lego Mindstorms RCX controller...

Maybe it's in the Rayer genes? It isn't a common name...

There was an F G Rayer (G3OGR, SK) who was famous for writing constructional articles in the British magazines in the 1960s-70s. His trademark was that he continually reycled his junk-box of WWII tubes through a string of different projects, so we learned to greet the same EF50s and 6V6s like old friends!

Coincidence... or not?

Coming back to the original topic, it's a well-known corollary of Murphy's Law that "Amplifiers oscillate and oscillators don't."
The solution is therefore to rebuild your oscillator as an amplifier.

my suggestion is a 12AT7 butler type xtal oscillator with 33.333MHz
overtone xtal, and use 100MHz output which is fed to a 6AL5 dual phase
rectifier to double to 200MHz and another stage to double to 400MHz,
6AF4 seems fine for this stage

5338. Yaesu G-650C Antenna Rotator Schematic

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-08 08:11:31 UTC
From: la8ak@online.no
Message-ID: <3b99cf45.312684356@news.online.no>
Source record: 50433

Purchased Yaesu G-650C, but no manual followed,
opened the box and it looks like it is somewhat same principles as the
DAIWA CR4/P in a more integrated way, the only device I could identify
is the 12V regulator

I am curious, and wonder if somebody has a circuit diagram for the
rotator?

The advantage of this rotator is that the pointer is loose, fixed with
a screw. As a rule I used end-stop at 270°, this rotator has 90° more
rotation, so with this rotator CCW end stop is 270° and clockwise end
stop at 360°

5339. Re: Problems with UHF oscillator that doesn't (using tubes)

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-08 11:08:48 UTC
From: William Rayer <noone@nospam.com>
Message-ID: <M0nm7.19554$592.2899564@news2-win.server.ntlworld.com>
Source record: 50435

Thanks for the feedback everyone. I accept your point that it may be
easier to build UHF gear using semiconductors. I don't know, as I
haven't tried. It's good to see radio amateurs (also s/w developers)
building UHF equipment. I just prefer using tubes, that's all. It's a
reaction against the onward march of technology in my real job.

Don't worry, I'm not going to pollute the spectrum with this stuff.
I would not build a UHF osc to use as a transmitter, anyway my
UK licence lapsed when I moved overseas. I just like building
things, and I would eventually like to build a tunable convertor
to cover some UHF (70cm), but before that I want to build an
oscillator that I would calibrate using Lecher lines.

The purpose of the oscillator is (1) I will build a lower power
version as the local osc for the convertor and (2) I want to
generate a signal to "find the band".

TV tuners used to have a valve L/O to about 900 MHz. Surely
I can do this with a 6939?

Cheers Bill

5340. Circuit drawing program

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-08 11:31:50 UTC
From: Don Vosper <don@vosperd.freeserve.co.uk>
Message-ID: <9ncvji$3a4$1@newsg3.svr.pol.co.uk>
Source record: 50436

Hello
Can anyone recommend a schematic drawing program with a good selection of vacuum tubes.
I had a good one but lost it due to a crash and can't remember the name. The shareware vesion allowed 50 connections and was very easy to use.
Thanks
Don.

Sounds like me Bob. I am a software engineer by trade, but I studied
as an Elec Engineer before moving into computers. Recently I've become
interested again in RF and moved back to HAM radio and in particular,
Homebrew construction.

I dunno much about valves/tubes, only just having completed my first
tube project (which you can find on my website, it is a tube
regenerative receiver with a semiconductor audio stage).

> The converter idea was a bit further down the track. Before doing
> that I wanted to get an oscillator working properly, that I could use as

I built my own dipper for UHF using a BFR91, a small tapped loop for
the coil, and a compression trimmer for the tunable bit. It isn't
wonderfully stable, but enough to prune antennas. My signal generator
can only do up to VHF so I use it for a UHF signal generator too.

> I'll be more specific and ask some questions:

Don't know how much I can help, I have no experence with tubes at even
VHF.

> 1. Should I use PTFE tube bases, or is a ceramic base OK?
>
> 2. What should I use for insulating material for these frequencies
> (say 400 to 1000 MHz). Is ceramic OK? Perspex? Tufnol?

For solid state microwave stuff I normally test material by nuking it
in an microwave oven for a few seconds, if it gets hot, I try something
else. Even if it has low dielectric losses, it still can have a large
dielectric constant and make accidental caps so large your circuit will
not oscillate.

> 3. At the moment I use a 1/4 wavelength line as the tuned circuit,
> but the frequency of oscillation is not determined by the length
> of the line (it's quite a lot lower). How can this be?

I've found lines are not really good for this, I normally make a
gimick-cap style line and prune it down to where I want to thing to

resonate. It never seems to be geometrically related to frequency, it
is a suck it and see procedure.

> 4. Does my 1/4 wavelength line need to be in an screened
> container? At the moment I pointed it away from the tube base,

I normally just leave mine hanging in mid air inside the screening box
that encloses the entire device.

They probably aren't too stable either.

If you use unix instead of windows I'd try xcircuit. (It will run on
Win32 if you have an X server though)

http://bach.ece.jhu.edu/~tim/programs/xcircuit/

I recently have discovered it, it is very handy for making diagrams
even if the interface is a little weird at first. On the xcircuit site
there is a few contrib libraries of tube symbols.

Because of stary capacitance and inductance inside the tube and
especially the socket, and perhaps slightly because of transition time
in the tube.

>2. Next I tried a single triode in a colpitts circuit. This used the same

Same problem.

You need to use a nuvistor or a very small tube with short leads,
close spacing internally, and no socket opr a very comnpact socket.

>I'm using a tuned line for checking the frequencies. The 7pin
>tubes used a PTFE base, but I used a ceramic base for the 9pin.

>
>Has anyone done experiments with these tubes/circuits?

About 40 years ago I built a 70cm AM transceiver. I used a tube that
had the grid and anode leads out straight through the envelope, and
although the line had to still be shorter than 1/4 wl because of the
tube loading the line I was able to easily reach 440Mhz.

I finally modified that transmitter to use to give antenna lectures
and demonstartions using light bulbs and wires, but eventually had to
abandon it because it was too unstable and started causing QRM to
two-way systems in the early to mid 70's. I remember doing an antenna
demonstration in a meeting room below a bank, and having police
surrounding the building. The transmitter set the vault alarm off.

The transmitter use a tube that looked like a doorknob, but I forgot
the type number. The key is short leads, small elements, close
internal element spacing, and no socket.

For Ian's benefit only, don't get nichrome near the oscillator!

Source record: 50443

Thanks for the feedback everyone.

G30GR was my Dad, he really got me started building transistor circuits in the mid 70s. But the comment about the EF50s and 6V6s is a bit unfair :-) I think there was only one 6V6 in his junk box. And no EF50s. And he did a lot of transistor and IC projects in the Babini books in the late 70s / early
80s, xtal controlled 2m transistor lo power tx, and a scope project.

I think the idea about zapping stuff (insulators) in the microwave to see if they're OK for UHF is brilliant. I never thought of that. Pity I can't do that
with the tube bases! But I will do the zap at 1KW test for any insulators that I want to use (perspex etc).

Also the comment on the resonant lines was interesting. I've gone through my copy of Terman's handbook, and from what I understand twin parallel lines shorted at the end should form a 1/4 wave line, assuming the spacing is not more than about 3 or 4 times the diameter. But in practice i have not found this to be the case.

Does a parallel line transmission line need to be enclosed for it to work?

Also I use enamelled Cu wire. (14 swg). I will get some 1/4" solid copper rod and try this later on, and see if it helps.

I don't know if I need little chokes for the heater/cathode connections. I try and avoid chokes if possible.

I still think a reasonably stable UHF osc should be possible using tubes.Think of a TV tuner. These used EC86/PC86 tubes as ocsillators up to about 1GHz. I think I'm just making mistakes in regard to layout or component types, and I don't have the experience to know where.

All the best
Bill

What was this resonant line made of ? If it was some kind of coaxial
cable, you have to include the velocity factor and also the effect of
the stray capacitances.

The reason I'm having problems is because I don't have much
practical experience building VHF/UHF circuits. This is a hobby,
it's not my job. And I prefer using tubes, because I live on the
planet Zog and semiconductors haven't been invented here yet :-)
On Zog the periodic table has unknown elements with atomic
numbers 14 and 32...

I agree with you. I think they would have poor frequency
stability and would generate harmonics. I would not use
one of these circuits for a transmitter.

>cable, you have to include the velocity factor and also the effect of
>the stray capacitances.

It is a parallel line shorted at the end, made of 14 swg enamelled copper wire (about 2mm diameter). The spacing is approx 2 wire diameters, about 4 mm. The entire line is 15cm long (ie a total length of 30cm, bent in half to form a thin hairpin type arrangement). It is free standing, ie soldered to the tube base and sticking up in the air. My RSGB radio handbook says these lines can be made from enamelled copper, plain copper or brass (but not tinned copper).

In case the line is too thin, or the enamelling is no good, I plan to get some solid 1/4" copper rod and use this (spaced by about 1/2"). Also I will need some kind of insulator to space the rods. An earlier reply to this news group suggested zapping the insulator in the microwave to test it at UHF, so I will do this.

Whether I use transistors, tubes or whatever, a resonant line should still be resonant at the calculated frequency (+/- say 10%) surely? This is what bothers me....

Cheers

Hi,

In the various issues of the RSGB book VHF/UHF Manual you can find
oscillator and amplifier circuits with valves. The oldest one I have
is from about 1969, and there is a lot of nice valve stuff. Converters
for 23 and 13cm with valves!! Old issues of the magazine VHF
Communications have also circuits with valves.
Free running oscillators on VHF/UHF is a very difficult task to get
stable. A common circuit was some kind of a push-pull with a double
triode like ECC 81 or better, but the usual way was to use a stable
free running oscillator at a low frequency and multiply it in several
stages. Or a crystal oscillator with multiplying. Or a free running
oscillator mixing with a crystal oscillator etc.

There is a lot of common and cheap valves that is very suitable at
UHF. EC 86/88 and PC86/88 is usable up to about 1300Mhz
The pencil valves like 6263/6264 is usable up to at least 1700Mhz
and is rather cheap. There is a lot of others, too many to mention
here.

Try 3/4 wave length line. It should work as well as 1/4 but might be
easier to make. Don't forget the leads inside the tubes.

> Does a parallel line transmission line need to be enclosed for it to work?

It doesn't have to be enclosed. Radiation could be a problem if the feed back is
weak.

Insulation should not be the problem.

Why not simply use a semirigid coax section as the resonator. At least
some old 450 MHz cellular phones used these in the VCO. A microstrip
resonator has been used in some 1.3 GHz FM-ATV projects, although I
guess that the Q is not very high with ordinary PCB materials.

>I still think a reasonably stable UHF osc should be possible using
>tubes.Think of a TV tuner.

The required frequency stability requirements are not that hard.
Assuming the video IF bandwidth is wider than necessary (adjacent
channels are usually empty at a specific location), the oscillator
could drift more than 1 Mhz without too much problems. The video was
envelope detected anyway and the sound IF taken from the video
baseband after the video detector, so the audio separation did not
need much frequency stability.

Bill,

The leads into the device, and capacitance of the device, load the
line and make it look longer.

You may have missed where I said that.

You need a device wih direct leads out of the valve, small elements,
and no or minimal socket stray inductance/ capacitance !

You do not have that.

From my point of view, I'm affraid there is no one chip solution. The solution you describe don't give a perfect 50-50 signal. Do you need such a signal ? If not, you can also consider the following solution : multiply the frequency by two with a simple RC circuit and a XOR gate, then divide the resulting frequency by 5 with a one chip counter.

I think I'd divide the 10 MHz by 5 to get 2 MHz and then multiply by two.
Or, if you need a good 50/50 duty cycle, multiply by four and then divide by
2.

Even normal coax cable makes very low drift oscillators on 30-40MHz,
QST had an article where RG174/u was used, but if you have teflon
cable - semi-rigid or not it is much easier to solder.

I hope that someone out there reading this message knows how. We have a new baby girl (QRP) here as of today! Bringing her home today caused some new problems. The new baby seats require that infants must face the rear of the car. My wife nor I can see the little one without doing major contortions (I drive a Dodge Neon). I have a little CCD video camera here and an old Sony Watchman (QRP TV) that could make a dandy mobile baby monitor. I would like to add a video in jack to the Sony. I do not have a schematic for the set. This was a popular mod to do as many CCTV installers had units modified to do this. (Sony made a Watchman minus tuner built for this purpose but at $350.00 many companies bought the regular watchman @ $99.00 and added the video in jack.) Anyone know how to do this? I could figure it out if I had access to the schematic.

Thanks in advance,
Randy KB8ASO

Maybe 2600 volts no load. Although like you i have seen homebrew linears with much higher. Maybe with the cheapness of these tubes some are going crazy. I heard of one operator driving a pair of these tubes in excess of 3.3KW out!! Considering the 3rd order IMD this clearly is a bad practice. If you are seeking greater out put, look at a pair of GU84s, or a single GU78. Better still find a 4cx5000 or 10000 you can get superb 3rd order IMD. If power is your game. A pair of 800s make a nice desktop homebrew amp, i have used 4 in parallel with a low plate impedance and a small roller inductor. The balancing and matching of these tubes get critical. One tube with handles is better.

Willy

The microseconds in the equaliser is referring to the delay introduced
by the equaliser.

Are you sure the meter isn't using in MicroSiemens which are equivalent
to micromhos?

1. The time constant of the standard R/C de-emphasis filter for FM receivers is 75 microseconds. That describes a roll-off at a rate of 6 db/octave or 20-db/decade. The value specifies the frequencies involved.

2. I have no idea why microseconds would be used on conductivity meters. Unless, what you are calling microseconds is really "milli-siemans" the new unit for conductivity. Mhos is no longer used.

With a couple of passive components, I suspect a single chip solution
is straightforward.

Feed the existing 10M into an RC shaper (or a mono) and then double it
with a full-wave bridge or similar. Then do your divide by five from
an 74xxx90.

Still, that won't produce 50%; the '90 MSB is 20%, isn't it?

I think that whatever precedes it, the last stage must be a divide-by-two. If that is preceded by a divide-by-five, I have to multiply up to 40MHz; a pair of fast cascaded delay/XORs will do that but the second needs about 12nS delay, only a few gate delays in ALS. 40MHz based on race timing is unsettling; is that unwarranted?

The suggestion to divide down to 2MHz then multiply to 4MHz is good but getting 50% is trickier.

If I go down to 8MHz by counting four-of-five (80%), then divide by two (50%) with a '90, '196 or '175 and an '02, it seems much more trustworthy. Am I wrong?

Actually, 10 MHz divide by 5 and then multiply by four would result in
the 8 MHz which can be divided by 2 for 50% duty cycyle.

I would think that two stages of X2 multiplication would be fairly simple
to do and it doesn't require any exotic divide ratios.

'fraid so. As pointed out in an earlier post, counting four-out-of-five gives four pulses at a ten MHz rate and a gap. Dividing by two gives two pulses at a 5 MHz rate and a gap - not a 50% duty cycle as you hoped. Have you considered using a 4 MHz VCO which you could phase-lock to the 10 MHz reference?

And I'd be more comfortable producing 8 than 40MHz, too. Good thought.

It looks like an HC4046 will do 4MHz easily. If I divide the 4MHz VCO out by two and divide the 10MHz reference by five and feed them to the phase comparator, that should work, yes?

I would think that you could do the divide by 5 then multiply by 4 and the final divide by 2 all in a single chip, although the multiply by 4 would probably have to use two X2 stages and use gate delays....

Still, a single chip seems 'nicer' somehow as a solution. If you felt like it, make a gate as the oscillator and the entire thing boils down to a crystal, a couple of caps and a resistor, and a programmable array logic chip.

Using a CD4046 would need perhaps three chips, since you could use the 7490 as the divide by 5 for the 10 MHz and also the divide by 2 for the VCO. You would still need a loop filter and watch out for the phase noise.... 4046 VCO's are noisy critters.

From: "Sverre Holm (LA3ZA)" <svholm2@online.no>
Message-ID: <xjQm7.12940$1T5.145090@news1.oke.nextra.no>
Source record: 50381

I was using a Leader LSG-216 signal generator for my first home brewed QRP rig. After having gotten several RST xx8 because of a slight instability in the frequency, and a slight hum modulation of the tone, I found that both problems originated in the signal generator.

Does anyone have similar experience? - and is this what can be expected from a PLL signal generator?

Or does it indicate that the signal generator is out of adjustment? I have noticed that the DC voltages are slightly off in the generator. The +/- 15 V supply is 15.2 V and the 5 V is 4.85 V. Would it help to adjust them?

Or -- a much large project, that probably is hard -- could the loop filter in the PLL be modified to get a better short-term stability, at the expense of e.g. a larger settling time when the frequency is altered?

Any help and comments would be appreciated.

Has anyone any experience with basic stamp projects? I am looking to build a channel scan board to step through 4 crystal controlled channels in a UHF receiver. All I need is a way to assert a sequential ground to each crystal, and have the circuit stop on open squelch activity, optionally I would like some priority logic for one channel. Has anyone done this?

This sounds like it would be very simple to do with a Basic
Stamp, but that seems like a bit of overkill for the task.

Perhaps a PIC (a low end one) would be more suitable. Or,
even the ubiquitous 16F84 would do the job.

No I haven't done exactly what you ask.

Were you using just the signal generator barefoot as the transmitter
into an antenna? I would not be surprised if the signal generator was
noisy/unstable due to the load. You might isolating the signal generator
from the antenna with a buffer amplifier.

Also, how were you keying the generator? It's possible that the way
you were keying it was causing it to re-settle on every key-down.
That could even sound like hum/etc.

Thanks for the questions and the interest. Here is my response:

No, I used one transistor as a buffer amplifier in front of a push-pull
stage consisting of 2N1711's. Output approximately 1 Watt on 80 and 40 and
less on 20 m.

>Also, how were you keying the generator? It's possible that the way
>you were keying it was causing it to re-settle on every key-down.
>That could even sound like hum/etc.

The generator was running continuously, while the base circuit of the output
stage was keyed. It made no difference if I also keyed the buffer stage.

The problem is that I hear both the hum and the random instability also if I
just connect the generator to a receiver

By my count that's four packages, but it's apparently better to give the XOR phase comparator two 50% signals, so 1MHz looks better despite requiring two more flops.

Why a VXO, though? If it's locked, wouldn't RC work as well?

If you just want to step scan, consider using a decimal counter like a CD4017, a transistor array, and a 555 multivibrator to set the period for each step. You can rig the '4017 to count in increments of 4. The cost would be less than $5.

Interesting situation here...

As of the time I am posting this, N1RZB had received a total of eight responses to his inquiry, and not one of them had anything to do with answering his question! Instead of helping the guy, everyone gripes and whines about cross-posting!

Yeah, I know that there are both written and unwritten rules of "netiquette", and perhaps N1RZB shouldn't have posted his query to some of the groups that he did post to. But perhaps we need to take a closer look at this. What's happened to the hobby? What's happened to hams being helpful to each other? Instead of getting an answer to his question, all he gets is bitched at by a bunch of self-appointed "interenet cops". We keep hearing that ham radio is "dying out". It's no wonder! When someone can't get a straight answer to a valid ham radio question, or get ANY answer in this case, it ain't hard to see why people aren't sticking with the hobby. I've heard it said that the internet is killing ham radio. This is a perfect example!

I wish I *could* give this gentleman an answer, but I really have no personal experience with six meters. I'm sure I'll be flamed for cross-posting this message, and for being one of the people who isn't giving the guy any help. At least I'm WILLING to help... I'm just not ABLE to help.

From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <9nigidbko1@slb4.atl.mindspring.net>
Source record: 50392

It has been my experience that a lot of PLL sig-generators use a wideband vco to keep costs down. Add to that a small step size and the designer has to use a narrow loop bandwith to keep the reference sidebands liveable.

Which winds up with a tenancy to hum since the vco will have a mind blowing tuning sensitivity. And, usually. some amount of low frequency jitter since the vco has very little noise reduction through the narrow loop filter.

The better performing generators do a much better job of it, but it requires a lot more parts and hence cost a lot more money.

For most Sig-Gen purposes, the residual hum and noise is not too great of a problem, and they work nicely as rouble shooting and alignment tools.

==========

Generally, there is no easy way to improve one of the 'noisy' generators to make them quiet. I don't know anything about the specific generator you mentioned, but I'd think it is probably working about a well as it is going to...

I've been looking at the new RCI 5054 (over Internet not in person yet) and thinking it didn't look like to bad of a deal ($300), I just wish it had the tone board already installed and not an 'add on' like it is now.

it is easier to go from 10 to 8MHz and divide by 2 to get 4MHz,
74HC4017 (?), HEF4017, 7493 or other in the first stage

Zero crossings will be correct as described for divide by 5
With the possible danger of getting glitches, it is theoretically
possible to use combine (Q0 and Q1) with (Q5 and Q6) with a NOR-gate
for higher duty cycle output

I have scrounged up a big quantity of .1 uF Polyester/Metal Film caps. These, according to the databook, are equal to ceramic disk caps in all uses. These are NOT NPO caps. Made by S+M Components.

How about 50 for $3 or 100 for $5.00 500 for $20.00 (they're abt 15 cents each from Mouser) I ship in a 4 by 7 padded envelope.

These are .1 uF, 10%, rated at 250v - New Stock, on paper tape, nice long leads. Good for bypass caps I am told. That's what I have used them for.

I still have NEW BNC chassis connectors for

25 for $12.40
50 for $21.00
100 for $36.00

I also have:

LM7808CT voltage regulators. TO220 case. 5 for $4.50, 10 for $8.00
LM7812T voltage regulators. TO220 case. 5 for $4.50, 10 for $8.00

22uF 35v electrolytics - $5.00 for 100 (if you need larger or smaller qty, email me)
These caps are on paper tape, NOS (New, but old stock) made by Richey.

2N2222's in METAL TO18 case - 25 for $7.50

Let me know if you're interested. All prices are post paid to the USA.

Thanks - My address on QRZ is good.

Message-ID: <3b9cda7c$0$2882$44c9b20d@news3.asahi-net.or.jp>
Source record: 50298

Hullo Don

Heheheh! This is a repeat of a conversation I had over on rec.audio.tubes...I was also looking for a cool circuit drawing prog that I had BEFORE the last unscheduled re-format of the HDD...All I know for sure was that the link came from a ham radio page and the guy there also recommended "Socket Watch"...My searches for that page were fruitless, but I'll just paste what I said to the other guy:--

QUOTES ON

I still haven't found the package I've been looking for, but you could do a lot worse than try this one, CircuitMaker Student:

http://www.microcode.com/downloads/student.htm

I've just DLed it and it seems every bit as easy to use as the one I had formerly. [And yes, I checked, it has a 'reasonable' set of vacuum tube outlines in its library!] This 'student version' is only good for 50 devices, tho...

HTH
Adam

PS: If you do choose to DL it, make sure you choose "Run from current location". It will install quickly and easily and be ready to run. You don't have to close your browser to install, either. It's probably just a lot better if you don't have any OTHER progs running at the same time. Cheers!

QUOTES OFF

I don't think the other guy tried any of the recommended packages...Before the thread developed very far, he said he actually LIKED drawing circuits by hand and scanning them...Oh, well!

Best of luck, Don
Adam

From: Skipp <skipp@pilot.ucdavis.edu>
Message-ID: <9nivfbjcp1@woodrow.ucdavis.edu>
Source record: 50299

Hi there,

Maybe it's me, but I think your labels are off a bit. Do you mean filters from a 900Mhz purc unit..? and if so, that's quite a bit different than what you are actually writing.

So you want to use 900 Mhz cavities on 450 Mhz and the answer is "sometimes". It has a lot to do with the physical construction of the cavities. Some will allow you to use them in "folded" mode at a lower frequency, but it's a little past the scope of a news group topic. Some 900Mhz cavities are actually normal 450Mhz cavities operated in 3/4 wave/mode. It takes a bit of experience and test equipment to know what is what.

It's not a lot of information, if your really serious about trying to convert, modify or retune the cavities... contact me direct and I'll try to help you as time allows.

cheers

That's the trouble with using "canned" formulae,... you
never can see where they come from;;;;

Consider the following:

Field strength (watts/m2) = Pt Gt
(the RADAR equation) -------
4 * pi * R * R

Power captured by a receiving antenna:

Capture area (m2) = Gr * Lambda * Lambda
----
4 * Pi

(Lambda is the wavelength in meters or 3e9/ F)

Now, combining, the power down the receiving antenna is
the product, --- the field strength in watts per sq meter times
the capture area in square meters.

Note that "lambda" is a frequency term. This is what you were
asking about.....

It is a result of the physical dimensions of a low frequency
antenna of a given gain being larger than the physical dimensions
of a higher frequency antenna with the same gain. The larger
physical dimensions mean more microvolts since it has a larger
capture area.

Anyway, now you know where to look.... Good luck...

>
>You need a device wih direct leads out of the valve, small elements,
>and no or minimal socket stray inductance/ capacitance !

Fair point. I have no way of calculating the effect of the stray
capacitances
and inductances of the valve socket. I know the values of the strays inside
the valve, but that doesn't help regarding the socket.

Also, someone pointed out that even if the socket was OK for UHF, it
may have a high dielectric constant. This could multiply the strays a lot.

Some of my radio books (Terman and the Radiation Laboratory series)
say that above about 1000 MHz you have to use valves without bases
and build them into cavities (exactly as you said). I was hoping to
approach this frequency without cavities and special valves, to make the
construction a bit easier.

Thanks anyway for the suggestions everyone. It has helped.

Cheers
Bill

> What's happened to hams being helpful to each other?

Unlike you, Dean, I don't have any poignant predictions to make about the future of the hobby, but it is VERY clear what will happen to the newsgroups if people aren't discouraged from cross-posting to ten groups at once. THAT insight doesn't require any soul-searching at all.

What the original poster did was every bit as much a part of "the hobby" as tuning up a 2KW transmitter in the middle of the band without bothering to turn on his receiver first. Crossposting to 10 unrelated groups is an act that could only indicate careless naivete on the part of a newbie, or extreme discourtesy on the part of someone who should know better. A quick check of Mr. Moge's extensive posting history on Deja will reveal which of those two options is most likely to apply here.

Followups set to the appropriate group...

I'd like to know what a minimalist link budget might look like for 902 MHz EME.

1) Does anyone have experience with what a path loss for 33 cm might look like?

or

2) Where might I look this up?

Thanks!

Jake Brodsky, AB3A mailto:frussle@erols.com

Thanks for comments. The Leader generator with the hum/jitter problem has a
range from 0.1-30 MHz + 88-108 MHz. Is this what you mean by a wide range?

In comparison, my Elecraft K2 tranceiver has a VCO that runs between 6 and
24 MHz. Elecraft calls it a wide-range, band-switched VCO. Perhaps the
difference is that the signal generator covers each range without
band-switching?

in this case OR gates sums, one must practice logic to see it,
with OR or NOR gates logic 1 is significant while zero is significant
for construction with NAND gates,
so what you do is to combine Q0+Q1 AND Q5+Q6, which means that you use
two NOR-gates and a NAND-gate, and later decide how to connect to use
only one sort of gates. I am more familiar with NAND and NOR gates
than OR and AND gates

You must study the inner circuit of the logic device you use and
decide how suitable this is for your circuit, but dividing from 8 to 4
makes 50% duty cycle using JK or D-type FF

Perhaps so, but I am looking for an entry project to learn programming of the stamp, and have that immediate application, so thought I would start simple, and build upon it, like adding remote DTMF control, etc. later on.

I am looking for an old GLASS, broadcast tube. Eimac number 750 TH It is about twice the size of a 4-1000A. I do not care about emmission. All I want is the filiaments to work for a lited tube display. Socket also if available.

Or any other GLASS tubes of that caliber or larger for the display.

Is there any commercial source for bakelite anymore???
Or is there a good decent looking substitute.

Have heard of abs sheet which is black and pvc sheet
which does not come in black, these are easily worked.

Also heard of black lucite but have heard it is hard to
cut and drill without cracking.

any ideas sources or suggestions appreciated.

Nedd a couple of panels about 12 inches square.

thanks

Hi Jake,
Path loss is -259dB. The equations are in the ARRL Micrwave Experimenters manual. I have not operated 902EME but on 23cM, a 10' dish and 250W and a polarizing feed (ala VE4MA circular) will yield echoes. My concern at 902 would be that it is very lonely. 23cM, on the other hand, is very active- not unusual to hear guys ragchewing on SSB off the moon.

> band-switching?
>

Yes, the Leader Generator is wideband, since it covers .1 to 30 MHz as a single band. That would imply that it actually uses something like a 80 - 110 MHz VCO that gets mixed down to cover the .1 to 30 MHz. If so, then the VCO tunes 30 MHz without switching fixed components.

For example, let us assume the tuning voltage is 0 to +15 VDC. That means an average of 2 MHz per volt. Which would mean that darn near any random noise coupled into the varactor tuning line will show up as a pretty big noise signal.

It also implies that the VCO will be extremely sensitive to any parameter shift. So, even the slight capacitance change in the transistor junction caused by a shift in the DC power supply is likely to cause the oscillator to shift it's frequency.

Oh yes, the large tuning range also implies a lower 'Q' resonant tank, which means the overall phase noise is going to be pretty noticable and that's not even taking into account the other noise sources that can couple into the circuit through the DC power or the tuning line.

It is possible to clean up some of the problems by widening the loop filter, but how far that can go depends on many things.

Wide range VCOs reduce parts counts, but getting good performance is usually not all that easy....

==========

The Elecraft is using a narrow band VCO and switching fixed components to get the total frequency range. Narrow tuning ranges mean a much lower tuning sensitivity in MHz/Volt and also usually a higher 'Q' tank.

> ... I figured that if you went to the trouble of deriving the 4Mhz from a xtal reference.you would want the best output.

Jim, you've convinced me that the VCXO/PLL is the right way to do it, comparing at 1MHz; I've got a 74HCT4046A in a breadboard already. There is a clear advantage to doing it that way: if the 10MHz reference is unavailable, I'll still have 4MHz from the rock - not as accurate, but better than no clock at all.

The application, BTW, is to replace the 4MHz oscillator on a 6803 that controls the Wavetek 288 function generator. All of the synthesis in the 288 is based on the processor clock. Mine is currently about 112.3ppm fast (+1223Hz @ 10MHz), and the design is not tuneable and can't be externally referenced. This will fix that.

Thanks, all, for your thoughts. 73

Sounds good to me. You might want to consider the Net Media
Basic-X 24, then. It is pin compatible with the BS-2, but
is more powerful, including multitasking etc. And it is less
expensive than the BS-2.

Good Luck.

Bakelite was the first commercial plastic, a thermosetting resin it has
excellent temperature and insulation characteristics.

Most of the thermoplastic resins you mention don't have particularly great
temperature characteristics -- that's why they are easy to work. You might
check in with Cadilac Plastics -- I beliveve it's a subsidiary of Hanna (the
largest compounder in the US.) Last I talked with them they were intending
to set up a website and sell in smallish quantities. You might find an
"engineering" resin which is not difficult to work.

On Harry's site http://hem.passagen.se/sm0vpo/
He has a page about reusing the TOKO coils
It says that ===
RED - Oscillator. With 30pf - 300pf = 1MHz to 2MHz
YELLOW - First 455KHz IF filter transformer
White - Second 455KHz IF filter transformer (not always used)
Black - Last 455KHz IF filter transformer
Can't see anything about the Orange one though.

Have you thought of circuit board? Maybe it won't fit your
requirements, but I've used it when I need some easy workable
material, and I've never had problems getting it locally. Use
single-sided circuit board, and put the copper side inside it
you don't want it showing. Or, take the copper off. For small
bits, I've taken the time to peel the copper off the board. I'm
not sure what the easiest method would be to strip a large board,
other than etching it (which seems a tad wasteful).

Yes, I have. I don't bother taking the copper off usually. But
sometimes you want a piece of easily drillable/cuttable material
that is non-metallic, and that's when being able to take the
copper off comes in useful.

When I think of bakelite sheeting, my mind immediately thinks
of circa 1930 and bakelite panels on the old regen receivers.
Despite the capacitance effect, they apparently did not want
a metallic panel. So in answering the original question, I
couldn't help but wonder if what was significant was something
without metal.

I find circuit board much easier to work with, using tin-snips
and drilling, than straight metal. In many cases, one does
not need the strength that metal supplies. I've made plenty of
little boxes by soldering small bits of circuit board together
(the copper not only supplies shielding, but aids in constructing
the boxes. A scrap of circuit board has to be pretty small before
I throw it out. You can make all kinds of brackets and fixtures
out of small pieces. And I have used circuit board as front panels.
I've used Sylvain's idea, cleaning the copper until it shines,
and then protecting the copper (I've used spray on Krylon) and
I find it makes a very attractive panel.

A comment in the thread about a tube UHF oscillator reminded me of K1CLL's numerous articles in 73, where he built all kinds of VHF and UHF equipment on circuit board. It sure didn't look pretty (when there were photos) but I think that sort of construction is less inhibiting to the beginner than looking at an article with photos of carefully machined metalwork.

Polished with a coat of urethane, labels and some more urethane
should make a nice (if unusual) front panel.

>here.

I was hoping to get a push pull circuit working with a double triode
or double tetrode. I'hve had some success with 6J6 and 6939, but
the only PTFE base I have is for the 6J6. The other UHF valves I
have are the 6AF4, 6AN4 (similar) and 6AM4. I would prefer circuits
based round 'normal' sockets, since it makes the construction easier.

I understand the pencil valves really like to use coaxial cavities.
The problem is I don't have lathes and things needed to make cavities.
I wanted to make it work with a copper transmission line, and maybe
the entire oscillator would be in brass or copper box.

I would like to buy or make a low pass filter for 2m VHF. I am currently running an all mode rig (FT-290) and a 50 watt amp. Where can I get plans, or a kit to build this type of filter? If there aren't any kits that exist does anyone know of a commercially made product that is inexpensive (I think DCI makes them and they cost big bucks) and readily accessible? The only ones besides the DCI low pass filters that I have been able to find are here:
http://www.progressive-concepts.com/12.html

I am open to any suggestions. Thanks for your help!!

For operation inside an amateur band, you don't actually need a filter
with a continuous lowpass response - you only need notches for the
harmonics. An extremely effective multiple-notch filter can be made very
cheaply out of coax. See the examples on my website.

They are very good at finding the "wrong" satellite.
There's lots of birds up there. Sometimes only a
real spectrum analyzer is able to sort out which
sat is which, and which polarization is correct.

If you want to use a high accuracy 10MHz external reference then I
guess this makes sense, otherwise, why not just buy a good "tweakable"
4MHz oscillator and install it as an independent clock?

Another possibility might be to just replace the processor clock with
something more accurate.

I have four 10MHz standard sources on the bench, all better than 1E-11; two of them are near 1E-12. No affordable standalone oscillator can do that.

Paper Micarta would be a good substitute. You can also use Linen Micarta. It machines and sands well. I am not sure of its use in hi Q circuits, or what its R factor is. You would have to be carefull in high power use. But check the GE site for info

Or you could do it in a PIC 12C508 with almost no external parts for a
(US) dollar. There should be just enough pins for 4 channels, a squech
input, and a stop/start/restart control switch.

Same chip as I used for a PIC morse keyer (see
http://www.owenduffy.com.au/electronics/pik/pik.htm)...

Yes.
Sorry, I directed the remarks directly to John who I saw to be a VK and so would not pay the tax. I didn't think to qualify the statement. Oops.

Cheers
Murray - VK6HL

You're right, Micarta is a thermoset -- last I heard it was made by Westinghouse, but since they've been gobbled up I don't know. Formica is also a thermoset. GE's plastics run to the polycarbonates and silicones.

willy wrote in message ...

5456. Yaesu's ADMS-1D cable substitutes for ICOM CT-17 CI-V box

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-12 18:28:54 UTC
From: jflanders2@home.com
Message-ID: <3b9fa94c.158977716@NEWS>
Source record: 50253

I needed to control /read my new ICOM 756PRO from WriteLog, and have been able to get the above cable working between the standard serial port of my computer and the input jack on the radio by only adding a Radio Shack 274-368 (1/8 inch stereo plug to 1/8 inch mono jack - $1.99).

With the RS adapter plug, the cable functions as if it were the CT-17, except that it only has one radio connector instead of the CT-17's 4.

Details: The ADMS-1D is a cheapie package (I paid $30 new 2 years ago) from Yaesu which contains software for programming some of the Yaesu radios (including my VX-1R) along with a cable to connect from the computer to the radio. The main cable includes an extension/adapter cable to allow the package to work with Yaesu radios having 4-conductor mini earphone/data sockets as well as 3 conductor ones. In addition, the cable includes a bidirectional level translator inside the DB-9 which converts to/from TTL levels.

Before trying with the radio, I plugged the cable into the serial port and read the cable's signal levels with a VOM and determined that the signal was on the center ring of the 3-pin plug and the common was on the base, and also verified that the tip was not connected to anything. Opening up the db-9 verifies that only two wires are used.

The Radio Shack adapter plug is intended to convert stereo phones to mono by paralleling the ring and tip signals from the jack and connecting them to the tip of the mono plug. Just what I needed to "move" the signal to the tip of the adapter, where it plugs into the 756PRO.

It works, and there is no mod or change to the cable - I can still use it when needed with the VX-1R radio just by unplugging the cable from the RS adapter plug and inserting it into the 4-conductor extension/adapter cable. Been going several days now with the 756PRO - no problems.

> I can do this with a 6939?

The first large-scale use of transistors in television sets was in the UHF tuner. That was a very long time before transistors came into wide use in other circuitry in televisions. (For the purists, yes, a few solid-state TVs existed in the early sixties, nearly all by Sony. That's not *wide* use.) That should tell you what a majority of skilled tube-circuit designers thought about tube UHF oscillators. You've picked a challenge.

This coming Sunday....

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday September 16th 2001
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all

sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)

Dear Miran,

In response to your e-mail request on the amateur radio newsgroup.

The company that deals with Toko coils in the UK is Roxburgh.

The Toko specialist is Louise.early@roxburgh.co.uk

The main site is www.roxburgh.co.uk

I hope this is of some help to you.

Best Regards 73 etc.
Geoff G8PPQ.

Hi there

Bill Janssen wrote in message <3B9E9F15.A05B048B@ieee.org>...
>If you want to tell me where in the world you are located and/or give me a
>Email address
>I can consider sending you some parts that may make your effort easier.
>Bill K7NOM
>

Thank you - that is a very kind thought. I live in Guernsey, off the south
coast
of the UK. My email is 'lingolanguage@hotmail.com' but you have to type
the address in. YOu can't just reply to this posting as I set up a fake
reply
address to cut spam.

Also I think my problem is not using the parts I have got properly. I
assumed
I could just wire up a circuit and it would work. But for UHF I think I have
to
be more patient and experiment more, eg get something working anyhow,
then make a single change and retest, and slowly improve the circuit by
that method. Often I am not very patient, I like to wire things up and have
it work directly!

The news group has helped a bit, I've picked up some ideas and learnt
some new things.

All the best
Bill Rayer

Yes - that's an interesting idea I have not considered! Maybe the
7 and 9 pin socket tubes don't go so well above (say) 500 MHz.
But I've seen a circuit of a 70cm RF amp using a 6939 that had
about 0.5W in and produced about 5W (1961 RSGB handbook).
WOuld that imply an oscillator could produce 4.5W on that
frequency, in theory? (This is theory, I realize a L/O should
produce more like 4.5mW, not 4.5W)

regards
Bill Rayer

Thanks for the ideas, the PIC 12C508 looks like a pretty cost effective way
to go. But I probably will eventually go with something with more
horsepower, to build upon.

Hi Joe,

If you start off with a PIC 12C671 you will be code compatible with the 16x PIC family. There are a wide range of parts in the line. If upgrading to more complex stuff is an issue I don't think there is a better family out there.

But can you get phenolic circuit board anymore? Maybe I've
been mistaken all these years, but I always thought phenolic
circuit board was that cheap and crummy stuff that was brown
and shattered when I cut it with tinsnips (and when etched,
the copper traces had a tendency to come off the board when
you were soldering). Whatever it was, it was what I started
with because the local old-style (it wasn't "old-style" in
1971) electronic store had that for sale. After a few attempts
at making circuit boards with it, I found a different source
and I was done with that cheap stuff, that I thought was phenolic.

I don't recall seeing that stuff in years. What I see is epoxy
of fiberglass epoxy. Easy to cut without shattering, strong,
and the traces stay on. Probably useful for the need in question,
but not phenolic.

Message-ID: <u4TjuPAHdQo7EwyX@invest.fsbusiness.co.uk>
Source record: 50271

I was recently sent a copy of 'Circuit Maker'.

Now this seems to be just a schematic capture and simulator package.

Can someone please confirm this?

If so then I'm still after a basic s/w pack to put a simple QRP AM TX
circuit to PCB.

Can anyone help?

Many thanks

Phil G4ZOW

Hi Harold.

For starters, I could use a schematic.Would you be interested in selling your copy of the manual? I am thinking of using it as a longwave receiver (20 khz and up). I will need to build a high impedence preamp to match a voltage probe type antenna.

Thanks for replying,

Ralph Lane

From: "Sverre Holm (LA3ZA)" <svholm2@online.no>
Message-ID: <Pqco7.16326$1T5.183012@news1.oke.nextra.no>
Source record: 50273

Anyone experienced with HP service? - or strange ICs?

I have an HP 5326B counter from the seventies that suffers from low sensitivity, about 50 mV rms rather than 5 mV rms as the specs say. The frequency range from 0 -50 MHz is fine, actually it is OK up to about 70 MHz. I have tried to understand the input stage in order to figure out where the loss occurs. There I came across an integrated circuit with 6 pins in a TO39 size can (same as a 2N1711, except 6 pins). Its designation is 5-334 7038 and it has a symbol that I think is that of National Seminconductor (looks like an N on top of an S).

Does anyone know anything about this IC, or better yet are familiar with the input board of this counter (type no of board
is 05326-60003).

Thanks a lot

Sverre

For parts, if you must do it yourself (I haven't seen many broadcast
variables on EBay) consider salvaging the innards of a Swan 350 or Eico 753.
Of course, you could also salvage a variable cap from a broadcast receiver
on EBay.

Sorry Phil I can't help. But while you are making enquiries,
writing SOS letters to the newsgroups, waiting for a lot of useless
replies, trying to download the right software, you can sort it all
out for yourself with some paper and a ball point. The circuit is
simplicity itself.

It probably won't work first time anyway. But Good luck.

Reg.

Where have you looked? QRZ.com thinks you live in
Tacoma, and that outfit on Puyallup Avenue have stacks
of what you're looking for. Pricey, yes, but that's the
nature of the game now.

You might ask local hams for variable capacitors.

You might check and see if there is any junk equipment
around that might provide one - thrift stores are usually
a good bet. Old analogue-tuned FM radios are usually
a better bet for ham projects.

You might try a ham swap meet. There are several
good ones in the Puget Sound area.

You might try DDS tuning and avoid the issue entirely.

Hi Jason,

Try this place for variable caps, they are faily reasonable,

http://www.oselectronics.com/

Also you might try 2nd hand stores and yard sales to find old BC radios, I scrounged two nice variable caps and a couple of 455KHz IF filters from two old tube BC radios that I got for 50 cents each just two weeks ago.

For projects, try this page

http://www.geocities.com/CapeCanaveral/Hall/8701/hamfiles.htm

Bry dosen't have a whole lot of files of his own but he does have hundreds of links to pages that have homebrew projects. One of those pages should have what you want.

You can also try researching back issues of QST and get a copy of the ARRL Radio Amatuers Handbook. The hand book is a pricesless guide to the homebrewer.

If you are interested in homebrewing with tubes, let me know, I have a lot of sites you can go to as well as some build it your self articles I could send you.

Another place this frequency range is monitored is in gas leak detectors. I believe they heterodyne the ultrasonic frequencies down to the audible range. However, you'd have to use something besides simple heterodyning if you want to cover the whole band from 20-100 kHz, since you could only hear less than a 20 kHz band at a time. (Quite a bit less if you're older and/or your ears have been abused.) You'd need a way to compress an 80 kHz bandwidth into much less. It'll be interesting to see what ideas people come up with.

Roy Lewallen, W7EL

It's not like all bats chirp all the way from 20kc to 100kc. In
general smaller kind of bats chirp in higher frequency regions than
larger bats. I don't know the English names for examples.
What you could to is use a mixer IC that has a build in oscillator and
make the osc. tunable between 20-120kc. (a simple rc config will do).
Then locate some small electred mic, and follow it with an amp that
has a highpass frequency response, to compensate for the freq.
responce of the electred.
After the mixer use a simple lowpass filter and small audio amp.
Now you can tune the receiver until you hear the chirps.
After a while you should be able to recognize what kind of bat you
here by its sound and by the reading of the scale.

Check http://home.zonnet.nl/bertrik/bat/bat_indx.htm
for examples.

Hi Christer,

The simplest idea would be to build a simple heterodyne receive converter using a CD4046 VCO (DC to 100KHz) feeding a simple mixer (BF981 or similar). Those transducers you get in misical Christmas cards work well as microfones, well into the ultrasonic spectrum, that would be the second input to the mixer. LM358 will amplify and drive "freestyle"-type headphones.

I have already searched for transducers for a totally different type of project and found them to be typically $300 (SEK3100) as a starting price.

The majority of bats emit sounds below about 70KHz. You would have to travel abroad to find bats above that frequency, but certainly not in Sweden. If you want a bit of fun with them, then build an "up-converter" and play their recirding back to them. I did that using a parabolic reflector!

You might want to take a look at Mallory's website article on snubbers.
What kind of surge are you trying to eliminate.

Well, variable caps are sort of passe.

There are 2 problems with variable caps, they are expensive, and for setting frequency they don't have enough mechanical range. Yes, if you can cobble up a design using a broadcast cap which you can get at a decent price, and sometimes you can even find a broadcast cap with a built in reduction, but you are still left with way too much capacitance for most of the ham bands. And if you put another cap in series to reduce the capacitance, you've clobbered the linearity.

If you bite the bullet and get a nice air variable (say from http://www.rfparts.com/) for some outrageous price, you still need to come up with some sort of reduction gear and dial arrangement, which is going to add a ton of change (and complexity). Heck, the cap and dial can easily end up costing more than the entire rest of the rig!

The more modern approach is to use DDS, but the parts are hard to find and expensive, and the design is pretty tricky. Unless you can find a VFO kit (there still seem to be a few around) which will cost you a ton of change, you better have a good spectrum analyzer because DDS, improperly designed, can end up with spurs in all sorts of unexpected places.

Probably the most common homebrew solution is to use varactor tuning. There are a number of varactors available from http://www.radioshack.com/, http://www.fix.net/dans/, and a number of other parts outlets over a wide range of capacitances. Typically the voltage (and thus the capacitance) is set with a ten turn pot, sometimes through an op amp. (See the designs from http://www.qsl.net/k7qo/swl30.pdf, http://www.qsl.net/k8iqy/, http://www.redhotradio.com/Smk1bsch.pdf or http://www.redhotradio.com/Rh20_1.pdf).

In fact, if you look at K7QO's MH101 project (http://www.qsl.net/k7qo/), you may well get a lot of ideas.

Frequency readout is a little bit of a pain, ten turn dials are available but sort of expensive, and you need some sort of calibration chart. A digital readout is a lot more convenient and can probably be put together at lower cost (get cheap LCD's from BG Micro).

Hope this helps

Mallory makes snubbers called "Quench Arc" but they are used for a different
purpose -- across relay terminals etc.

AudioXpress has just had a series of articles dealing with garbage on the
A.C. line., mostly relating to the degradation of performance due to
harmonics etc.

Not really and necessarily always true. One of the most effective
suppression systems on the market is built around a large inductance . . .
as I recall it uses NO MOV devices. Tradename is something like Brickwall
(?). Try a search for more detail.

Jason

One note - I mentioned B.G. Micro for LCDs, and I have used their LCDs successfully on a lot of projects. Their price is second to none. However, George Heron, N2APB, reports that they are very finicky which may be why they are so cheap. I have to admit, it took me a while to get my code working on their really cheap 16X1 LCD's ($3!!), but once I did, that code seemed to work on all LCDs with the Hitachi controller.

If you go the LCD display route, you may want to consider going the long dollar for a nice LCD from DigiKey or Mouser, but the availability of a cheap, working LCD for a lot of projects made the dinking around I did with the B.G. Micro LCDs well worth the time, IMO.

Well i followed some of the links you provided and ended up at Small WondersLabs. they have resonably afordable kits which is a plus for me. atleast their sw+ series look fairly afordable. the rest are just slighltly out of my price range. Unfortunately it is either cw or ssb with the kits not both. Was wondering 1 if these are good projects for the first time builder and two how hard would it be to modify the cw kit for both cw and ssb operation? Aside from combining two kits into one box....I noticed they had a little pic controled freq counter at swl as well for 20 it's output is in morse was wondering what the opinion is on those. Little bit of background on myself..

Retired Navy Cryptologic Technichin communications/ Maintenance...i changed carreer tracks from operations to electronic maint. after becoming a ham.. Figured i would do something that interests me more. I'm trained in component level repair/soldering... The only problem is i have a head half full of knowledge due to injury thats why i was retired.. so ni i finally have the time to do projects but i need to relearn alot of the theroy.

There are excellent kits out there, and with the difficulty
you're having with parts procurement, this might be the way
to go.

Brickwall, Zerosurge, and Surgex are series mode protection. I defined MOVs as the active component in the most effective surge protection - shunt mode. Series mode protection acts as a dike on hot (black) and neutral (white) wire. It provides no protection on the safety ground (green) wire. If installed as a dam to stop a flood, then the flood simply overflows or breaks the dam. But if installed as a dike, then series mode protection divert the flood downstream where it does not damage.

Obviously, the flood is a surge. A dam provides no alternative path for surge flow. A dike depends on shunt mode surge protection to provide that downstream path. That is what shunt mode protection does - divert the flood (surge) downstream (to earth ground). Series mode protection only encourages more of a surge to seek earth ground through the shunt mode protection. But shunt mode protection must be installed.

IOW series mode protection is effective to supplement shunt mode protection. It also provides noise filtering. Noise does not require the up front shunt mode protection. But to properly divert a surge, series mode protection must have some alternative path for the surge to flow. That is shunt mode surge protection installed at the service entrance less than 3 meters to central earth ground.

Notice it is not any fancy circuit inside a surge protector that protects. It is the 'system' built around the most critical component of that 'system' - earth ground.

As noted earlier, series mode protection has its soft underbelly - the safety ground wire. All surge protection is only as effective as its earth ground. Shunt protection must include a superior single point ground. Series mode protection also requires, even moreso, that central earth ground be the best ground in the structure. Earth ground is the most critical 'system' component (so why do we still build new homes as if the transistor did not exist - existing superior earth ground remain unutilized?).

No earth ground (series or shunt) means no effective surge protection. That is the fundamental component of a surge protection system that ineffective plug-in surge manufacturers conveniently forget. How do you identify ineffective surge protection? They fail to mention critical earth ground AND provide no dedicated, less than 3 meter connection to earth ground. Ineffective surge protectors are 'system' components disconnected from the rest of the surge protection 'system'. A surge protector is only as effective as its earth ground - which ineffective retail manufacturers would have the public not understand.

The recommendation for Brickwall assumed series mode was unknown. However notice how little so many really knew about surge protection - even series mode vs shunt mode - and the most important 'system' component of all surge protection systems - earth ground. A surge protector is only as effective as its earth ground.

Jason

The SW+ series is an excellent first kit, even more so because of both the MH101 project (basically homebrewing an SW30+ and a project a while back where the a bunch of folks from the QRP-L reflector built the SW40+ kit. I think it was VE3DNL who kept all that stuff on his website, and there's a bunch of information on the QRP-L archives, which are both online and available on CD. This series gives you the opportunity to dig into the radio piece by piece and develop a really good understanding.

I took a quick look around and VE3DNL's stuff is at
http://www.qsl.net/kf4trd/faq.html

Initially, I think you spoke of a receiver. There are a couple of issues with receiving SSB. First, most of these single bad radios cover between 70 and 100 KHz of the band. The SSB portion is somewhat larger than this, so likely you would need to choose a portion of the band to listen to. Moving the range would entail nothing more than removing a turn or two from a toroid. Chances are you could broaden the range, too. That would likely take some experimenting, probably changing a cap and readjusting the toroid.

The other issue is the passband width. The SW+ series has a narrow passband for SSB. If you look at the 3 crystals in series on the schematic, you likely would need to bypass one or more of those, or perhaps fool with the values of the 2 capacitors. Again, not a terribly difficult thing to do.

Transmitting SSB is another matter, however. That would be something of a project. Still, not totally unreasonable.

The little Morse frequency readout is a kind of a neat thing. I have an NC-20 (which is the pre-RedHot RedHot 20) which has this. It is kind of nice, but it does make operating an entirely different experience. Since you never need to look at the radio, it somehow feels different to operate. Not at all unpleasant, however.

Laura is right that a kit is a much lower pain way to go. There really is no thrill quite like operating a completely homebrew radio, but collecting the parts is quite a hurdle, and getting things to work takes a lot of patience. Perhaps worse, a lot of the parts tend to come from different sources, so the shipping can make a one-off homebrew rig quite a bit more expensive than a kit. If you plan some more building and stock the junkbox, then successive radios can be quite reasonable, but the first time out, you will probably need to go to 3 or more suppliers, each with a $5-25 shipping fee. If you don't plan very carefully, that can really add up.

Oh yes, on the PIC. The little PIC readout is nice, but it's a problem offering those for all the possible VFO configurations. Dave has the one

for 20, I think assuming a 5 MHz VFO, and somebody else (I don't recall who) has one that can be set for your combination of VFO and IF. However, they are surprisingly simple to do yourself. There is a startup cost ... a PIC programmer costs about $10 to build (less if you don't buy the parts at Radio Shack), the software is all available free, a PIC costs $6, the crystal it needs 0.89 (DigiKey), add a 5V regulator (0.39-0.79 depending on where you buy it) and a couple of caps (maybe $1) and you're in business.

As some of these posts show, bat detectors have been around for a while.
The earlier bat researchers used high speed portable tape recorders
to record the echolocation pulses. You can play the sounds back at
lower speeds and get a very nice rendition of the sounds. The "churp"
sound of the so-called "FM" bats (e.g. Eptesicus fuscus, common in North America)
is difficult to appreciate with these mixing type bat receivers.
The downward sweep of the sound is just a click to the human hear until
the sweep rate is reduced along with the frequency. To get a good
recording, you need a broadband ultrasonic microphone. The ones I am
familiar with are capacitance type that use about 100 volts of bias.
My experience is outdated now, so perhaps there are alternative methods
available. Over the years there have been a number of circuits and
articles published on building your own dectector. However, I have not
seen an article on usings an A/D and D/A on a laptop computer to
do "real time" slowdown of bat sounds for human listening.

The classic book on bats and their sounds is: Listening in the Dark
by Donald Griffin.

>
>
>
it is at least two ways.
1) One is to use a bit-rate generator,
2) another is to use SN7493 or similar device. I wrote some notes
about application of this device, you can see it at
http://www.qsl.net/ok1cdj/dubus/8603-1.pdf , but the author changed
the device to 74HC92, so you cannot see the trick from this page.

Since it was based on experiments carried out 16 years ago it is
difficult to trace notes now, I cannot even find any data sheet for
7493 TTL device, not even the Motorola LS-TTL databook, perhaps I find
it later, then I will report back, but the trick is to connect the
4-bit binary counter as divide by 10, the trick doesn't necessarily
work for a BCD-counter, but 7490 might work, I am not sure today. You
must study the truth diagram often shown in the databooks

3) the third suggestion is to use 4017 or similar decimal counter
where two outputs are connected as to suppress two out of 10 pulses, I
would suggest Q0 and Q5, then it is 4 and 4 pulses

it may cause some glitches, but such is easily filtered using a simple
LC-bandpassfilter on 8MHz, and not much Q-value is needed for pure
8MHz signal. I saw this type of application on circuit diagram for my
Apple 2E+ computer

Thanks for the advise on the kits...Of coarse i have just had a huge
revelation after viewing the arrl site...The whole licensing structure has
changed and along with that i'm not sure what else has changed.. I am
classed at tech+ what frequency privledges does that allow me? Suppose I'll
have to just do some studying. I'm up in canada right now anyway so i'll
be getting my ticket here too soon enough.

You have the same privs you did before restructuring, however you now have no need to pass any further code tests. General and Extra have the same freq privs as they did prior to restructuring. The FCC will no longer be issuing Novice, Tech+, or Advanced class licenses.

My suggestion: When you get back into the states, advance! You'll love the new privs. I know I do.

Good luck,

Henry C. Gernhardt, III

Message-ID: <3BA5E86A.4409195B@norpak.ca>
Source record: 50229

Hello All
I am trying to figure out the proper way to wind coils.
for instance when the schematic calls for a 1 turn coil
Is it really a 1 and 1/2 wind?
Same for 4 turns is it really a 4 and 1/2 turn.
I've looked around and cannot find a source of info
on proper coil winding. Can anyone please enlighten
myself on coil winding or point me to a source of info.
Thanks in advance
Regards
Frank

If you're talking about toroids, you count one turn each time the wire passes thru the center of the toroid.

In both cases, your really want to try to stick with the
number of turns listed. A 2 turn air-wound coil has
the wires both coming out in the same direction.
How you connect those wires to the circuit without
adding 1/2 turn is your problem.

In my usage, a conductor that comes out of the pcb and goes back in
counts as one turn.

IMHO, yes. Bear in mind that the inductance is related to the "core"
cross-section, so if a specific inductance is required then the shape
of the loop (particularly a one-turn loop) is important.

As mentioned in Tom Burns post Part is a dual N channel FET. The part was made by Siliconix. Siliconix part number was DN377. This information is from 5326 manual. The HP cross reference does not show a cross for this part. In worse case you could put two seperate N channel FETs in place of the dual. Tom WB6IQD

Thanks for input. After I got the information about the dual JFET I have traced the circuit and I have started to doubt that there is anything wrong with the input stage after all.

The amplifier consists of a differential JFET input stage followed by two more NPN transistor differential stages that goes into a differential common-base stage. This is where the voltage gain occurs. After that follows a differential Schmitt trigger. Now in my counter, everything seems to be working fine, all DC voltages are balanced correctly in the differential stages and the signal can be traced from stage to stage.

What confuses me is that I can read from the HP product description on http://www.qsl.net/la3za/HP5326a.pdf that the input sensitivity is 5 mV, while my counter has a sensitivity of 50 mV uniformly from audio to 50 MHz. If you have the manual, maybe the value for sensitivity can be verified?

Sverre

Yeah let's bomb the Afghans. That'll make us all feel better and let's face it they can't fight back much. I seem to remember bin lid's name being bandied around with the bully boy's threats after the Oklahoma bombing too.

Evidence would be nice. I can't believe that security agencies who didn't see this coming can have suddenly gather irrefutable proof about anyone. Then again who needs proof if you are the most powerful nation on earth. Just bomb some third world country and then bully everyone else into saying you were right with economic sanctions. As the hysteria rises we are coming dangerously close to a witch-hunt with all the finesse of the McCarthy commission's investigations.

We should not let our justifiable sympathy with the Americans lead us into blindly supporting an unjustifiable act. Remember it was our sympathy for the Jews after WWII that led us into evicting the Palestinians from their homes to create the state of Israel that got us into this west vs Islam conflict to begin with. The USA and UK created this problem. Time we tried to sort it out with something other than superior firepower.

On the up side though, a war is always good for the economy. Instability boosts
arms sales. Yeah, come on, bomb someone - let's face it, anyone will do.

>of the loop (particularly a one-turn loop) is important.

It depends: for toroids, one turn is one pass through the centre of the toroid. The main magnetic flux path is through the core, and anything that looks like only a "half-turn" will in fact be made up to a complete turn by the external circuit path from the finish of the coil back to the start. The layout only affects the flux leakage from the external return path, and that is usually much smaller than the main flux inside the toroid.

But were talking about air-core solenoids here (or at least, the original questioner was). For this type of coil, the main magnetic flux path is much less well defined, and leakage inductance may be more important... but it doesn't actually matter! What matters here is to be able to copy the inductor from the *conventions* that the author used to specify it.

Conventionally, solenoid coils with "whole numbers" of turns have a right-angle bend at the start and finish, so the leads are in line with the central axis of the coil when viewed from above. The leads can go downwards at right-angles into a PCB, or be bent outwards at right-angles parallel to the axis, but there's always a right-angle bend involved at each end.

A hairpin loop is conventionally called a "half-turn". Solenoids of 1.5, 2.5 turns etc all have both leads coming out in the same direction when viewed end-on. When viewed from above, the start and finish are at diagonally opposite corners of the coil.

I hope those word-pictures make sense, without making me draw it in ASCII Art!

Hello Alec,

Given that our Intel capability was crippled by the Church commission
in the 1970's and Clinton continued the trend, we did miss this. But
it takes time for a report to be analyzed and acted upon.

Perhaps you can suggest an approach. Your success with the "Irish"
problem would seem to qualify the UK as "experts".

All the best,

John (Ex-USAF and wishing he could be on just one more flight)

Hi, I'm about to build the EconOceanic crystal shortwave set
http://antiqueradio.org/econmain.htm
I was just wondering, is there any way to build a crystal set without needing to have it grounded? I'd like to make my set portable. Most portable radios don't need to be grounded, and I'm curious as to how they get away with it. If I can do away with the ground, is it possible for me to still build a set with high sensitivity? Thanks for your help.

It's our failure with the "Irish problem" that should stand as a stark reminder at this time. You cannot kill an idea no matter how many bombs you drop. Someone will always continue to fund and support these terrorists just as the Americans supported the IRA and all those other terrorist groups world-wide though at the time to be in America's interest. Bombing the wrong people just creates more support for them.

By all means exact retribution, but come on we all know what is going on here. American public opinion cries out for revenge NOW. CIA and NSA have been embarrassed. Someone must pay. Let's make sure it is someone with no oil and no way of fighting back. Anyone will do.

Now who have we been waiting for an excuse to kill ?

As for a suggested solution, I liked the bugs one above

Alec (Ex British Army and wishing our wet bloody liberal's would have declared war on PIRA then)

What difference does it make who has bastardised the good Jaguar name Yank or Kraut. Don't kid yourself with the high morals attitude. If Japan hadn't attacked you'd have stood by and done nothing, Britain would have been defeated and you would have worked out some way of making money out of the Krauts instead of us. All that bothers me is this moral bullshit you all come out with. If the US says it's ok then it must be. I mean come on. Wake up. Your government has lied to you before and will continue to do so, it is almost as devious as ours. What about the syphilis experiments, radioactive iodine in school milk (done over here as well by the way)

I think you've had more than your money's worth out of WWII now don't you ?

> ps. How are your "pacification efforts" going in Ireland?
>

Not well. The IRA terrorists funded by AMERICA have proved hard to put down. Like the Palestinians, ETA and all the others world wide. I think the American public are deluding themselves if they think killing bin-lid is going to solve the problem.

Do not underestimate the power of the US military though, after all they managed to kill more UK troops in gulf than the Iraqis did. Which friendlies will get in the way this time I wonder ?

Alec

Not agreeing with US government policy makes me neither a supporter of those who commited this evil act nor a "dip-shit". What worries me is the apparent haste with which we seem to be chargeing into this so called solution.

Where is the evidence? Let's see it so we can all make up our minds. I for one have never blindly followed just because the government says so. Well, not since I left the army anyway.

Sorry we can't all share the same opinion, but I thought your country was the one who prides itself on upholding freedom of speech above all others. 'The land of the brave and the home of the free' or something along those lines. I don't seem to recall any small print under that saying "Only if you think what your told to"

well done Alex,i agree 100%,to me war and terrorism are the same thing,as it is in Northern Ireland we are not doing too bad,unfortunately the Ulster Unionists,have not grown up yet,when will they learn North and South are one country,and after last weeks attacks on schoolchildren we should just tell the unionists thats it.

but back to the issue in hand.

it has been a very sad week,with a large loss of life,and yes i despise those who have wreaked havoc on the US.
but the US has bullied people for years used chemical and nuclear weapons,policed who they dont do business with and let those they do use any method of oppresion available.

it seems though they dont like being told when they do wrong,and we now have to support whatever they say,funny that i thought i lived i a democracy.

bombing Afghanistan will not help,i hope Bin Laden and followers is dealt with,but why hurry,if we went in tonight,it would not stop the terrorist attacks,but increase them.

regards

At last. Someone capable of independent thought.

As for the Unionists, I cannot believe I risked life and limb for three tours to protect arseholes like that. The harassment of children is unforgivable, as are the actions of the parents for home publicity seems to outweigh the mental well being of their offspring.

Right and wrong seemed more clear cut then. But now I am coming round to the idea of unification and let them deal with or kill each other.

My main point in this is "What's the hurry ?" and "Less of the hypocrisy" i.e. America has supported terrorists for decades

Here's another good idea. Read the posts before you reply. I have 3 main points

1. Disgust at the evil act committed does not have to mean automatic support for anything and everything just because the US government says so. Conversely disagreeing with US government is NOT IN ANY WAY supporting terrorism against USA.

2. What's the hurry ? (to bomb someone)

3. Where is the evidence ? Let's see it so we can all make an INFORMED decision.

Alec

why is that we keep being told by the media,we all want war.

hypocrisy is having a field day at the moment.

one being its ok to go bombing Afghanistan,was not ok when the russians
tried ot though

also the refugees were only fleeing to get our dole??

but now its an evil regime in Afghanistan,so surely that makes those fleeing
legitimate.

as stated by Andrew and myself,we do not support the terrorism,but i for one
cannot see a reason for killing innocents in Afghanistan,with good
inteliigence and if we take our time using special forces may be we will
catch Bin Laden off guard,whereas anything in next 6 months is likely tro be
expected by him.

regards

OK, agreed, of course.

> 2. What's the hurry ? (to bomb someone)

No one appears to be in any hurry - a week has gone by...!
Who *honestly* expected retaliation within days? I certainly
didn't. It's going to take time to get forces in the area.
(Wherever that may be.) A few air-raids won't achieve much
in remote valleys and hillsides, will it?

You also said "As the hysteria rises we are coming
dangerously close to a witch-hunt with all the finesse of
the McCarthy commission's investigations."

What hysteria? I see measured talk at the moment. I read
your initial post in this thread as closer to hysteria than
any of the political talk I've heard.

> 3. Where is the evidence ? Let's see it so we can all make an INFORMED
> decision.

Ahh, here we have a problem. You're asking for evidence that
you have already stated is from doubtful sources. Who would
you trust to give you this information?

As it happens, I do agree slightly with you - but your
approach and posting style smacks almost of sensationalism.
Sorry, maybe I'm reading it wrong...?

Condolences to all in this terrible tragedy.

Different country then - united in one cause (almost) and helped with
copious amounts of cash and weapons from the west via Pakistan. CNN reporter
the other day described the state of the country now as "medieval".

They certainly won't be getting any Stingers now will they?

You do not have to support us. Tell your Prime Minister that his speech to Parliament was b.s. and you don't want to go along. I'm sure he'll understand, as will the survivors of the British citizens killed in the WTC attack. I'll bet you will soon all be lifting a pint together and agreeing that the USA is the demon. Cheers.

BTW, you do not live in a democracy, nor do we. We live in a republic.

A democracy is where there are ten people in a room and nine of them vote to kill the tenth. Furthermore, pure democracies are doomed to failure just as soon as everyone figures out they can vote themselves a piece of the public treasury.

Alex,
Thanks for your view point. I think most of us Yanks don't have a clue as to why a lot of countries hate us. In a recent CNN poll, over 90 percent didn't know what our foreign policy was.
We're not a bad people and we do hang our "laundry" out for everyone to see it. Maybe there is an answer out there somewhere to all this blood shed but I hope this doesn't escalate into something much worse. Just imagine what could happen if that "rug head" decides to spread a few biological weapons around the world. No one is safe and if he is eliminated, what would take his place? Scary thought isn't it.

Yes. Evidence would be "nice". In the aftermath, it's not at all unreasonable to expect some of the largest and most sophisticated global intelligence organizations to focus it's efforts and produce actionable information.

> CIA and NSA have been embarrassed. Someone must pay. Let's make sure it is someone with no oil and no way of fighting back.

Sir, you are truely an ass. If you think that picking the rotting, shredded corpses of friends, lovers and children from the rubble of our home is about saving face, you're a worthless human being.
I'm in the military and my 3yr old daughter saw my dog tags for the first time today. She asked, "What's these Daddy?". "That's a very good question" I said, not sure how to respond. "Why you have two?" she continued. I could only think to myself, "One's for my toe and the other gets shoved between my teeth if someone kills me." The thought of orphaning your children's painful but some things are worth killing or dying for. That's the gravity of which you speak and how much it means to us. It's not something you do in a rash moment. While I respect your opinion and, as an ally, would defend your right to express it,
You should be ashamed of yourself for littering this newsgroup with your inflammatory, inappropriate, poorly concieved views.
Good Night,
Drink, WP3JQ

Alec, with regard to your third point, neither you nor I are in any position to demand to see any evidence or to make any decisions. In our democratic nations, yours included, "we" make decisions through our elected representatives. So, no amount of public discussion and/or display or lack of display of "evidence" can have any bearing on the outcome.

It is good to ventilate and make people aware of your distrust of and anger with the US for whatever your reasons may be, but please do not discount and defame us all in your personal vendetta for revenge against real or imagined wrongs.

Speaking of oil, I must note that one of the VP8s I've worked (just to tie this
to ham radio somehow) doesn't count for DXCC because he operates from AN OIL
DRILLING PLATFORM. Would that have anything to do with Britain's 1982 escapades
in the Falkland Islands, a location that has great strategic importance to the
defense of Mother England, I'm sure.

Must be... you certainly seem to have more than enough sheep and fuzzy-headed
thinkers in England.

First let me express my deepest sympathy to the victims of the terrorist attacks in the US, especially to the Police and Fire-fighters killed (I work in the same field).

It would seem, at least to the rest of the world other than Americans, that recent American foreign policy has been driven by oil and little else.

The total non-involvement of the US in Rwanda and East Timor, as two examples that immediately pop to mind, would only seem to evidence this standpoint.

Once the mess has been cleaned up and the dead buried, Americans must take a long hard look at themselves. The American public must look at their country's foreign policy and try to understand why a large part of the global population hates them, or at best, puts up with them.

you really are an ars hole,and don't really have clue what your on about,this is a small group of people that have done a crime not just against the usa but the whole of the free world,nearly every nation on the planet lost someone from there country in this attack,and if there country does not defend its people,even if there not on there home countries soil,them there saying it ok for anyone to murder there people and get away with it just to prove a point.

most Muslims condem what happened

how ever this was a small group of people,who it is said but not proven was led by one man in Afghanistan called bin laden.

I agree that the usa must take some action,but to carpet bomb people who don't really support the afghan government and these people did battle for the usa against the ussr not long ago,this is really firing from the hip a bit.
all countries are running around that have had anything to do with bin laden,they are running scared encase they get drawn into this and get bombed,Pakistan is one,they don't care about the USA only aid that they will loose if they don't stand with the USA,millions of dollars of funding if taken away would throw the country into poverty worse than it is now.

killing more people will not solve anything,infact it may make things worse,and killing Muslims may draw more countries into this.

we need to go after these people and there group that did this,not slaughter more men women and children.

another american who does not like democracy,there are so many,but
thankfully not all.

what about the 3 yr olds in Iraq and countless other countries of the the
world,your hands have been in either directly or CIA involvement,the fact is
war is what we are are in already,every few weeks we bomb Iraq,and look what
its got you

5000 dead,you have disrupted the world too many times and now someone has
got you back,and for some reason its called terrorism,yet when you bomb a
country its called war???

to me there is no differance,its killing and its barbaric either way and who
ever is doing it.

to add to that all those capitalist bankers,and workers also are just as
bad,they wanted to get rid of the world trade centre and they did it.

io wish the stock market was brought to its knees in this country[not by
death].

regards

Hang on a minute ! No matter how terrible last weeks events were
(and terrible they were) I hope those in power will sit down & read Brit.
accounts of our disastrous 1st & 2nd Afghan Wars, to say nothing of recent
Russian accounts of campaigns in that country.
How do you fight a high tech war against a mountain based guerrilla
enemy who, although still trying to drag himself into something like the 15th
century, is quite capable of crossing 3 3000m ridges before breakfast (which
he probably doesn't need anyhow) ? Even after 26 yrs. in the military I don't
know the answer - but I do remember the poem written 100 yrs ago by
Kipling:

Arithmetic on the Frontier

A great and glorious thing it is
To learn, for seven years or so,
The Lord knows what of that and this,
Ere reckoned fit to face the foe -
The flying bullet down the Pass,
That whistles clear: "All flesh is grass."

A scrimmage in a border station -
A canter down some dark defile -
Two thousand pounds of education
Drops to a ten-rupee jezail -
The crammer's boast, the Squadron's pride,
Shot like a rabbit in a ride !

By everything you are indicating, you and whoever else should be happy about non-US involvement. But no, you aren't. Rwanda and East Timor didn't get their supposed fair share of foreign aide from the US. So, you are pissed if US does and you are pissed if the US doesn't. Typical of a spineless liberal.

Yes, global population (big generalization here and by no means am I lumping each and every person into this group) wants plenty of welfare/aide from the US with no strings/commitments. Free Lunch is another way of saying it. Global population wants US to play world police and take all the hits, and keep the bad guys at bay, but not on their soil, nor any inconvience to them, whoever them is.

Enough said.

5586. "Mathematics and Amateur Radio"

Newsgroup: rec.radio.amateur.homebrew

Source record: 50186

Frank,

It is always an argument, in particular for air-cored coils. Toroids are 'one pass through the center equals one turn'. Pig nose formers are contentious too, most people say 'up one hole, and back down the other equals one turn'. Slug tuned coils have large L changes with slug position, so a turn or so can be easily tuned out (you might still want to fiddle for best Q).

In either sense of the term 'turn' you can generally tune out the 1/2 turn 'error' by stretching or compressing the finished coil. It is a bit harder for 3 or less turn coils though (less material to play with). Diameter is probably the most important thing to get right.

Hairpins can be made large and distorted to tune, if you screw up and it won't align, rip it out and start with a different length of wire.

Sometimes the author of an article will include pictures or a more descriptive passage on the coils of a design. This is very helpful, as air-core coils are usually what beginners (and advanced construtors alike) have the most problems with.

If you aren't using a etched board, or a different layout to the original design, a 1/2 turn may be within the stray layout reactance differences, and experimentation will be required anyway.

You know, it is pretty easy to sit back in your comfy little country that hasn't had two major buildings flattend and 5000+ people killed in one day and blame the US for everyone's problems. No matter what we do, someone is going to be happy and someone is going to be mad. But when was the last time you or your little country trird to do something more daring then kick a bunch of under trained, outnumbered, who where they? Chillians? off an oil rich island?

If the tube is gassy you might try to run the tube with the plate a dull
red
color. As I remember the pate will take up gas as a kind of getter. This
only
works with tubes that have a tantalum plate.

MathCad, great program simple to use. You can buy add on engineering libraries that perform all the complicated engineering calcs. The best feature is, as you see the formula in the text you can type it in and instantly you have the answer. So simple.

Never spoil a good rant with the facts.

But you really should try reading a little - you know ... Books with
actual writing in... Not your usual comics.

You might then learn that USN warships were escorting supply convoys
partly across the N.Atlantic, long before Pearl Harbour.

American seamen were on ships being torpedoed and sunk, long before
Japan attacked.

There were even American officers working at GCCS, long before they
officially entered the war.

What with the constraints imposed by Congress and the law. FDR was
doing pretty much all he legally could - and then some. Long before
December 1941.

Wood by name and wooden by nature ... Eh? Alec.

Old Nick.

What makes you a "dip shit" is you are sitting here claiming someone
is rushing into something, like a massive bombing of countries that
sponser terroists, when nothing of the sort is happening.

What makes you a "dip shit" is you think somehow that rounding up
people who are known to be terrorists or who are in countries
illegally and questioning them is "charging into a situation".

Perhaps dip shit is the wrong word, you are more like Chicken Little
running around saying "the bombs are falling" and whining that no one
is gathering evidence when the EXACT opposite is happening.

You either aren't very smart, or this is just an intentional troll to
get attention.

Regards,
Tom

1.) We have laboured under American sponsored terrorism (NORAID) for
about 35 years, and we just lost another 300+ in the Trade Centre.

2.) America was not being blamed, but thought before deed would maybe
a better idea.

3)The Chileans had their country fucked up by Mr. Henry Kissinger, and
the Nixon government who couldn't see the point of democracy for
anyone else.

4)We happened to point out that maybe fascism wasn't a good idea, and
telling you about it, and informing the US intelligence agency about
Pearl Harbor, which was ignored.

One last point, Americans don't live under American foreign policy,
everybody else does.

: I would like to buy or make a low pass filter for 2m VHF. I am currently
: running an all mode rig (FT-290) and a 50 watt amp. Where can I get plans,
: or a kit to build this type of filter? If there aren't any kits that exist
: does anyone know of a commercially made product that is inexpensive (I think
: DCI makes them and they cost big bucks) and readily accessible? The only
: ones besides the DCI low pass filters that I have been able to find are
: here:
: http://www.progressive-concepts.com/12.html

: I am open to any suggestions. Thanks for your help!!

5610. Re: Input stage of HP 5326 frequency counter

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-18 20:50:28 UTC
From: "Sverre Holm (LA3ZA)" <svholm2@online.no>
Message-ID: <cqOp7.19841$1T5.234685@news1.oke.nextra.no>
Source record: 50107

I got it from the internet:
http://www.electronique-diffusion.fr/Accueil/Presentation/Gentilly/Mesure/Frequencemetre/5326a.pdf
http://www.electronique-diffusion.fr/Accueil/Presentation/Gentilly/Mesure/Frequencemetre/5326c.pdf
and http://www.helmut-singer.de/stock/1305662250.html, where the last sentence says "Beide Eingangskan�le besitzen eine Empfindlichkeit bis hinunter zu 5 mV." = Both input channels have a sensitivity better than 5 mV.

However, your number is right, my audio and RF-generators indicate 50 mV rms sensitivity for inputs A & B and 30 - 40 mV rms sensitivity on channel C. So I guess that is how it should be. It confuses me still to see the information in the brochures quoted above.

So that's what got me on the search for the extra 20 dB of sensitivity, which would be nice to have, but that I never found ....

Thanks for all help from various people in looking up their manuals.

Sverre

your mention of the Falklands has nothing to do with anything,i for one would gladly give them back to the Argentinians,i dont support current war

world war 11 there was no choice,but everything else since has been just to support the arms industry,i have a contact in the MOD [high up].who told me the reasons for Kosovo was mainly to get rid of weapons reaching the end of there shelf life.

a very good reason for killing people,you really cant take criticism can you.

but to be fair both bush and blair and even our new opposition leader have made a few good statements since last week,but i hope they dont get drawn into foolish action because it will make them popular.

and there a lot of good people in the US dont think i dont know that,but lots of the current problems of the world have been caused by the policies of US and UK mainly,soi yes i knock my own country as well,the only loyalty i have is to mankind and not to any country.
regards.and we are not insensitive to the situation in the US and of course the grieving of people of 35 countries,but to get a better world we have to look at the way we do things.

regards and i mean that.

i was at the church service at the American church in London on sunday,and very moving it was.

i take it you can read as i cannot think where i supported terrorism.

i hope the they get bin laden and his hench men,i believe that taking time gsthering inteligence on those involved in other countries as there a still many "sleepers" across the world,which is very dangerous,after intelligence has been gathered,then special forces should come into play,backed up in the background by other troops,so yes military action will probably be needed,lbut not led by the polls carried out in US but by good military minds thinking clearly.

but make no mistake whatever the outcome of the action,terrorism from middle east and others will not subside and in fact will probably get worse,particularly by those who think its fine to get killed in the pursuit of there goals>

agreed,but people want value for money and scrapping would of been seen as a waste,whereas using them is better value.

MOD Procurement work in mysterious ways,as do most government departments of all countries,they have there own agenda.

You're confusing a little wing-nut group with the US Government. Your
little internal street battles are a somewhat different issue. I know,
I know, the CIA is behind it all...thats cut and paste rheotoric.
When a hijacked 757 tries to park in the middle of EC2 maybe you'll
realize that your petty little preoccupation with NORAID is because you
have nothing better to worry about.

If the terrorist hide among the sheep (innocent people), which they are, and the sheep will *not* help or point out the terrorist, then some sheep will, unfortunately, need to be slaughtered. If you don't remove the cancer, it will growing bigger and stronger and be harder to eliminate in the future. Who places the sheep in danger? Terrorist or the people going after the terrorist? I say the terrorist by hiding among them. As has been mentioned, people who support and aide the terrorist are terrorist too, so they are no longer innocent.

War is hell.

Frank Worm <fworm@norpak.ca> wrote:

>I am trying to figure out the proper way to wind coils.
>for instance when the schematic calls for a 1 turn coil
>Is it really a 1 and 1/2 wind?

Consider a loop shaped like a Croquet wicket, soldered to a PC board.
It should be considered a single turn, because the rest of the circuit
on the board closes the loop.

If you think about it, any coil you wind and install in a circuit will
have an integral number of turns (once you consider the whole circuit
loop), otherwise both ends aren't connected to the circuit.

Likewise, you have to remember that the inductance you get depends on
ALL the area enclosed in the loop, so the circuit traces on the PC
board affect the total inductance.

I got my license in the Viet Nam era. My first day at high school we had mass for a young guy (alum) who had been shot down.

But, overarching is the notion of a "just defense". If we don't take immediate action to end the activities of this lucifer, we are going to suffer the consequences again.

I am selling BRAND NEW LCD display modules, made by Data Vision, model number DV-16400. I have over $25 invested in EACH ONE of these.

Asking $12 each (minimum 2, please)

I bought over 1,000 of these for a project that I have decided to abandon (no more time), and I want to sell them ALL immediately. Offers considered for large quantities, OR the entire lot.

Picture, detailed PDF documentation, and manufacturer website link is available at;
http://members.aol.com/ecc81/yardsale

Please respond BY EMAIL to < OvrReactor@aol.com > if interested.

Thanks,

Ah, I see now...

Attack America and it is the start of a terrorist war, loss of innocent life
elsewhere is simply "little internal street battles" funded by "little wing
nut groups"

I suggest you put that argument to one of the many thousands (yes thousands)
that have been killed or injured by both sides of the irish tragedy. Or
indeed the families who have lost loved ones in terrorist actions in Spain,
Russia, India and Pakistan, Sri Lanka and any one of a hundred different
countries.

Don't get me wrong, I have the deepest sympathies for all those affected by the WTC outrage. I think that that day will stay indelibly etched on my mind as long as I live as one of the greatest attrocities of modern times. I also have no personal argument with you Bill or indeed anyone who disagrees with what I say. Stomping all over someones right to speech is what the root of this is all about. The point that I am trying to make is that terrorism didn't begin on tuesday 11th september, it was just a very tragic call to America to wake up and sniff the coffee.

Tim Wood

The difference between a terrorist and a freedom fighter depends on what side of the gun your standing ... anon

That is all true, but misses the point of the original question. The question is how to make a coil exactly like the one in the original design.

By convention, air-wound coils are described the way they look: a croquet wicket looks like a half-turn, it's described as a half-turn, and if you follow that convention you will make one just like the original. That is what matters to the person who originally asked the question.

I just want to point out the US has no extradition treaties with
Afghanistan, so quite how they can threaten invasion of the country unless
one of its inhabitants is handed over is a mystery to me.

Then again, I guess extradition treaties don't work that well anyway.
Witness the IRA terrorises harboured by the US despite all our extradition
treaties

Wakeup, what you suggest (continuing killing of each other) has been reality since the beginning of time with human types. Only change has been the choice of weapons. Terrorism/war/fighting has/will continue. Right down to the last two people standing. You only start a fight if you are completely desperate and have nothing to loose or you think you can get away with it. Works for both sides. Innocent people (sheep) are used as shields or targets, or hostages, or camouflage, depending which side you are on.

A world I've created? No, one that we have inherited.

Stop the trend? Would be a nice wish. If you didn't go after the terrorist/bully, then it would be like playing the child's game of tag. Bad guy comes out and kicks the shit out of whoever and then runs back to *safe* homebase, where he is untouchable. He waits until the dust settles and then does it again but being more bold each time. Care to have the town bully living near you and he has a beef with you but the police couldn't/wouldn't do anything to him cause he was at his *safe* homebase? You can resort to saying *stop-it*, *stop-it* three or four times a day in your home and see if that makes a difference.

There *will be* a next round against the US and whichever country you want to talk about, even if we do nothing about the WTC case. Don't know when or where, but it will happen. Who are you kidding? There will always be copy-cats and there are still terrorist out there that have a beef against the US for legitimate/non-legitimate reasons. Rules have changed and for the worse.

A good defense is a strong offense.

Interesting. Any hard evidence seems lacking and the connection still looks somewhat flimsy to me. Of course if Bin Lid is responsible he would try to make it that way. Any murderer would try to arrange an alibi. But that doesn't invalidate all alibis any suspect may ever have, if it did a lot of innocents would be convicted of crimes they never committed.

It amused me where CNN detailed the beginnings of Bin Lid's network in 1979, using family connections and wealth to raise money for the Afghan resistance [to the Soviets]. They somehow forget to mention that he was funded and trained by the US to fight the Soviets.

Thank you All for your replies.
I was having a debate with an old coil winder who was
doing it wrong.(He was making a 1 turn a 1 and 1/2 turn)
So it was difficult for me to decide which was
the right way. After much study with your help
I may have figured out the right way .
Funny though, that there isn't a website or reference
in the ARRL books or anywhere on the proper "convention"
of winding coils. I guess it's something that's handed down
from one generation to the next :-)
Again Thanks
Regards
Frank

I think that the US has got more than it's money's worth out of the Lend Lease dollars from WW11. After all UK govts over the years have had to kiss the US arse whilst the US Govt (and I have no quarrel at all with the US people - I just think that some of the practices of it's govt leave a lot to be desired) ran riot over Central America, South East Asia, Mid East, etc etc. No country has totally clean hands, building the British Empire was a costly business for the conquered. General Kitchener was undoubtably a war criminal in today's terms, along with Cromwell and others.

It worries me just how much the average US citizen is manipulated by it's media. The coverage of the terrible tragedy in New York from CNN is undoubtably more simplistic than any other coverage I have seen.

I would fight for freedom but not the US Govts version of Freedom. I would fight for the right to be me and for others to have that right also, but I will not fight in a war for General Motors, Wal-Mart, McDonalds, General Dynamics and other US (and some European) multinationals which benefit from the current economic system

The attacks that happened in the US recently were an abhorrent tragedy and my heart is with the bereaved and the tramatised. Any man's death diminishes me which is why I worry abouth the unneccssary deaths which will occur if President George (Hardly Ever Traveled Outside His Own Country) W. Bush leads the world into a unfocused war which probably will turn into a war with Islam. At a time when we should be turning swords into ploughshares, Bush is turning ploughshares into swords.

I wish someone would sit down and give old George a history lesson, you can't fight terrorism with a wholly military solultion. Look at the nations (the US included) which were born in Armed Rebellion and which now take their place in the family of nations.

BTW on a slightly lighter note the UK will chip in to pay back the Lend Lease Dollars if you can take back things like McDonalds.

Sorry about the rant, I had popped in to talk about PMR 446 radios but when I saw the thread I just had to get the above off of my chest.

Best Regards

Marc

==========
In the field of mathematics, if you can add, subtract, multiply and divide, then you are already adequately equipped for amateur radio purposes. But this is not maths - it is only arithmetic.

I think what you need is a better understanding of elementary electric circuits. Once you understand how things work it is a simple matter to plug numbers into formulae. Only a knowledge of electric circuits, antennas, etc., allows the right formulae to be selected for the application you have in mind.

An important factor which links understanding the behaviour of electric circuits to arithmetic is units of measurement. It is necessary to think clearly in terns of magnitudes of the various units. Inductance: how many henrys or microhenrys ? Capacitance: how many microfarads or picofarads ? Frequency: 60 Hz or 144 MHz. Etc., etc.

It is necessary to understand only the simplest of formulae. Current = Volts / Resistance. milliamps = volts / kilohms.

To connect measurement units with formulae PRACTICAL EXPERIENCE IS NEEDED IN THE FIELD OF MEASUREMENTS. It is vital to be accustomed to to using simple measuring instruments. No radio shack should be without a multi-range, amps-volts-ohms, DC/AC meter. A radio receiver is also a frequency meter.

Someone has already pointed you in the direction of a good book which has simple formulae described in the appendix. There are plenty of others. ARRL and RSGB books give formulae in the text. Unfortunately article authors and printers too frequently don't have much idea of how to present mathematical formulae which can very easily be misread. Neither authors nor printers always understand what is being waffled about.

The safest way of obtaining elementary formulae is to go to professional electrical engineering text books for students. Purchase a notebook and visit a technical library.

WARNING - The most common instrument in radio shacks is the SWR meter. As useful as it may be, do not expect to learn anything

about measurements from magazine articles which purport to explain
what it does.

Basic trigonometry and algebra is useful, as is (at least) an
understanding of what complex numbers are (and how they're used).

I didn't go into the formation of my opinion but since you mention it, I can
assure you American TV shows had very little to do with it. Much more
important was my reading of US media and conversations with Americans over a
period of many years.

Anyway, I realise it's a sweeping generalisation and the vast majority of
Americans I know are really nice people... but I felt Wes deserved the
comment even if he was the only one in this thread to actually mention
amateur radio.

International law didn't stop the terrorists now, did it??

It's no mystery -- you either agree with the premise or you don't. As
the U. S. was attacked by a group known to be a "guest" of a
particular country, a country that is known to have harboured that
guest for a number of years, they can be considered a willing
accomplice. This is their opportunity to demonstrate otherwise, or to
become a target as an accomplice.

See how easy that is? You either agree or you don't.

>Then again, I guess extradition treaties don't work that well anyway.
>Witness the IRA terrorises harboured by the US despite all our extradition

Let's also mention that all those formulas involve the use of algebra in addition to aritmetic . . .

And dealing with most circuit theory and calculations involves dealing with vector quantities which basically are an excercise in trigonometry.

While I seldom diagree with Reg, and am not doing so here, I do want to emphasize that some familiarity with basic algebra and trigonometry eventually becomes necessary.

It is largely a matter of how far one wishes to extend his knowledge and capabilities.

As strange as it sounds, ordinary spreadsheet programs are quite
useful for calculating many kinds of many programs related to
electronics or amateur radio. After setting up the formulas, it is
quite easy to try various parameters (such as component values) and
immediately see the results. Visualisation of the result (e.g.
frequency response) is also easy.

The complex macro library comes with Excel can be quite useful for
electric and electronics calculations with reactances and impedances.

My point exactly -- it's clear which "rules" bin Laden and Afghanistan
follow. So what's wrong with the U. S. following now those rules,
since they obviously don't care for ours?

Hmm, I use Netscape 4.7 usually (although this machine is 4.51 I think),
and I find that ordering posts by "Thread" (not "Subject"), and focusing
on the preview pane, one can step through all unread posts by simply
pressing the space-bar. It even scrolls the screen for you when a
message is longer than 1 page - so from start to finish all I do is hit
the space-bar.... Easy!

|
|I think that the US has got more than it's money's worth out of the Lend
|Lease dollars from WW11. After all UK govts over the years have had to
|kiss the US arse whilst the US Govt (and I have no quarrel at all with
|the US people - I just think that some of the practices of it's govt
|leave a lot to be desired) ran riot over Central America, South East
|Asia, Mid East, etc etc. No country has totally clean hands, building
|the British Empire was a costly business for the conquered. General
|Kitchener was undoubtably a war criminal in today's terms, along with
|Cromwell and others.

Much of the commentary in this thread made by Europeans and you folks on the British Isles, seems to include the idea that Americans are hypocrites.

The very same commentators are from counties who I'm sure have behaved no less hypocritically at various times in their history, as you kindly point out above.

So, okay, America is a hypocrite. We also are the biggest, baddest hypocrite on the planet and if we decide to kick ass and take names then look out.

|It worries me just how much the average US citizen is manipulated by
|it's media. The coverage of the terrible tragedy in New York from CNN
|is undoubtably more simplistic than any other coverage I have seen.

Perhaps you are manipulated by your media and government and assume that the average American is too. Personally, I don't receive CNN, so they damned sure don't influence me.

That said, what is wrong with "simple" coverage? The strongest country in the history of the world has been attacked by a group of hanky-heads and they need to be killed. That is the essence of the problem.

My fear is that our government will talk this problem to death instead of taking prompt and decisive action. Frankly, I don't care whether you or the rest of the world approves or assists. It would be nice if you did, and I would welcome it, but I don't want to wait around while we all have a dialog.

See http://www.jewishworldreview.com/cols/sowell.html

(No, I'm not black and I'm not Jewish but I think this man has one of the better intellects around. And no, I'm not manipulated into agreeing with him, he agrees with me <g>)

|
|I would fight for freedom but not the US Govts version of Freedom. I
|would fight for the right to be me and for others to have that right
|also, but I will not fight in a war for General Motors, Wal-Mart,
|McDonalds, General Dynamics and other US (and some European)
|multinationals which benefit from the current economic system

The current "economic system" is what gave you the creature comforts that you most likely enjoy. Why do you condemn it? The "corporations" don't benefit, people do. As a shareholder in hundreds of corporations, I obviously benefit when they do well and, as is the current case, suffer when they do badly. Does that make me a bad guy?

And another thing, General Motors was turning out tanks and General Dynamics (Consolidated Aircraft) was building B-24s during WWII. Who was fighting a war for who?

|
|The attacks that happened in the US recently were an abhorrent tragedy
|and my heart is with the bereaved and the tramatised. Any man's death
|diminishes me which is why I worry abouth the unneccssary deaths which
|will occur if President George (Hardly Ever Traveled Outside His Own
|Country) W. Bush leads the world into a unfocused war which probably
|will turn into a war with Islam. At a time when we should be turning
|swords into ploughshares, Bush is turning ploughshares into swords.

Bush did not drive the aircraft into the buildings, nor did his or any American policy justify the action. Others drew the swords and I sincerely hope that they die regretting their actions. Their deaths will not diminish me.

Whether Bush is widely traveled or not is specious. Americans as a whole are not widely traveled, which gives you in the old country something to smirk about, but you must remember, we are busy WORKING, which is the engine that has created the world's greatest economy. If you are a ham (I'm not sure you are as this thread has spammed a bunch of groups) you should know that the American dollar is the universal currency. Our people may not be widely traveled but our currency sure is. Most of the countries is the world a clambering for some and figure we "owe" it to them.

The American devil isn't so bad when he's doling out the greenbacks.

|
|I wish someone would sit down and give old George a history lesson, you
|can't fight terrorism with a wholly military solultion. Look at the
|nations (the US included) which were born in Armed Rebellion and which
|now take their place in the family of nations.

You are being rather presumptuous when you assume that the solution Bush has in mind is totally military. Has he spoken to you personally and told you the plan? Whisper it in my ear.

|
|BTW on a slightly lighter note the UK will chip in to pay back the Lend
|Lease Dollars if you can take back things like McDonalds.

Is Mc still making burgers over there? I thought all of your cows were dead? I know we are shipping you butterfat so you can have your cream. I know that because I'm paying more for mine. So I guess I'm subsidizing England again with my dollars. Funny have this works:) It's probably one of those mean old corporations corrupting the mother country again. The CIA probably spread mad cow disease so our beef producers could make a few dollars.

I've posted on my web site a version of FDTD simulator code that contains a half wave 160 meter vertical above perfect ground. What is unusual about this code is that it outputs movie frames in the time domain. Using a volume rendering program called Animabob, you can see a 3d movie of the results. The code is also GPL.

I'm hoping some clever hams can help contribute to the project. The code is currently pretty simplistic, but it demonstrates the basic concepts of FDTD and perfectly matched layers for the boundary conditions. Later versions will include near to far-field transformation and S-parameters for the feed point.

Get it at www.members.home.net/europax

5682. OT : CW Bandwidth

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-20 13:47:18 UTC
From: ram <rmilne@aa.mbn.or.jp>
Message-ID: <9ocrf6$fd5$1@news.mbn.or.jp>
Source record: 50029

I apologize if this is slightly off-topic but among the newsgroups I frequent you are the only people I trust with this one.

I just read an introductory-level book on amateur radio by Harry Helms that says the bandwidth of a CW signal varies according to the keying speed and the faster you key the broader the signal bandwidth becomes.

My first impression was that the author might have become confused when he was writing this (since I could not see any reason why increasing the keying speed would influence the bandwidth) - but I just wanted to check with the group whether maybe he is correct and there is something going on here that I have not yet grasped.

Can anyone comfirm whether CW bandwidth does vary with keying speed? Is he talking about some sort of distortion when the key is put on/off due to the waveform not beginning cleanly at exactly the beginning of one cycle?

Many thanks, 73 ram G0WMF/7J1AUA

Ram

If we liken the CW to be effectively amplitude-modulating the carrier, then
the picture becomes clearer. Generally, in modulation the bandwidth is usually
twice the highest frequency of the modulating signal. If one could key quickly
enough, at say 1000 dots per second then we would be modulating at 1kHz
and the bandwidth would be 2kHz. Likewise for keying at 100 dots per second,
the bandwidth drops to 200Hz.

Therefore, we can easily see that the bandwidth is indeed related to the keying
speed.

Hope this helps

John, G4GOY
The views expressed are my own

Sure, think about amplitude modulation. A steady carrier will have no bandwidth other than the carrier itself. If you modulate it at 1Hz, you get some bandwidth taken up due to that modulation, or, modulate at 1kHz, you take up even more BW, right? In order to recover the signal (hear it), the modulation has to be using bandwidth proportional to the signal content being carried, right? Otherwise the information wouldn't get through.

Now for CW. What are you doing when you key the carrier on and off? Answer: You're modulating the carrier!

Turn it on and off at 1Hz, you're modulating it at 1Hz, keying at 1kHz gives modulation of 1kHz. How is this different from AM? Other than modulating at 100%, it's not.

Now, the actual BW used will depend on the shape of the waveform. If you are keying at a 50% duty cycle (square wave), the signal will have loads of harmonics since that's what a square wave really is, the fundamental plus the odd harmonics. So, keying at 1kHz will give energy at 1kHz, 3kHz, 5kHz, etc.

You can actually see this if you can find a spectrum analyzer to use. Turn on a carrier, you'll see a spike at the carrier freq. Modulate it with a 1kHz sine wave, you'll see a pair of spikes appear at carrier + 1kHz and carrier - 1kHz. Use a square wave and you'll see a series of spikes, decreasing in amplitude at carrier +- 1, 3, 5, 7, etc.

In any kind of on-off keying, this is exactly true. That's why the RTTY systems that operate over CW-bandwidths are all rather slow.

In practice, the speed at which a common 500Hz CW bandpass starts to affect the audible sound of the keying is up near the all-time human receiving speed, 70-something words per minute. So, if you've never noticed this effect, you're perfectly normal.

This gets more complicated by the fact that the human ear/brain system does not work in the mathematical way of integrating the energy in the signal to determine its strength; we "hear" the beginning & ends of the dits & dahs. So when the bandwidth available is trimmed back to what the mathematics says would be the limit, the code elements stop starting & ending crisply, they sort of fade in & die out. This is a tremendous disadvantage to our brains, who like the signal to be a touch "clicky". Computer code-copying programs can avoid this problem by using the technique of correlation, by comparing what they're receiving with a mathematical representation of a perfect dit & a perfect dah to decide which is a better match (yes, I know that's oversimplified). Since the noise produces the SAME error in both comparisons, it gets disregarded when the decision is made, only the signal creates a difference, so this is a very powerful signal-extraction tool. But, in practice, correlation requires precise synchronization of the keying & receiving systems: as many wits have noted, machine code-receivers work best with machine-sent code.

CW (on-off keyed AM) does indeed get wider with increasing code speed.

As you suggest, the keying breaks up the length of carrier observed.
Mathematically you need an _infinite_ length of carrier for the
transform to converge to a single line (Dirac function) in the frequency
domain.

The shorter the segment of a continous waveform 'observed' the more
possibility of it actually being a slightly different frequency and so
it inherits a probability profile in the frequency domain (one way of
thinking of it). That is to say, the observed chunk of signal contains
non-zero energy at frequencies other than exactly equal to the carrier
because they are required to cancel out the missing signal from the
beginning of time to the heat-death of the universe :)

If you correlate all frequencies with the signal segment you will
arrive at a number for each frequency which indicates its contribution
to the total envelope power of the signal segment. If the keying is
square, it will look sinc squared. If it is smoother it will tighten
around the carrier in a complex manner.

You could analyze the entire stream of CW if you knew the keying
pattern and calculate exactly what it looks like in the frequency
domain, but the answer would still be infinite in width with non-zero
terms going all the way out from the carrier to infinity on both sides.
For practical purposes you truncate it to where the terms get 'small
enough'.

Most people use the first null in the sinc envelope corresponding to
the shortest modulation period as the bandwith, and maybe add a bit more
for extra garbage like key clicks, because we all know CW keying isn't a
Nyquist pulse.

From the ARRL License Manual 1976:

"With proper shaping, the necessary keying bandwidth is equal to 4
times the speed in words per minute for International Morse Code;
e.g. at 25 words per minute, the bandwidth is approximately 100 cycles."

Keying a carrier with Morse code is just a form of AM. It
creates sidebands in the same way as AM phone or music.

Ok. I think this thread has gone on long enough. It really doesn't
have anything to do with Amateur Radio, nor the use of Amateur Radio.
I am not going to say that I don't agree with some of the people here,
but it would be better for us as Amateur Radio Operators, to show the true
spirit of our hobby by helping out with communications in any way that we
can.
I personally, have been helping out with the ARRL's National Traffic
System, but at this time, it appears that all communications have been
restored to the area. I was hoping to hear from people close to the
disaster, who could tell their own personal stories on the use of Amateur
Radio in the rescue efforts and with the survivors.

as usual ARRL has done a good job by all accounts,just as our RAYNET does in
the UK,so if thats it thats it???

over to anyone else,if they want to carry it on

wouldnt it be nice if all the worlds problems could be sorted by talking,it
would be a strange world if we all agreed 100% with each other,i know we
wont but at least we have managed to have a reasonable debate.

agree to dissagree as they say.

and if there is anyone who knows someone at "ground zero" pat them on the
back for me and tell them we are thinking of them.

I'll personally see to it that at least one person who hasn't been able
to catch the news in the past week knows that somebody on the other side
of the pond is in solidarity. We can't solve all the little petty
problems so easily, but this big one has the advantage of unifying
people. I doubt that aspect was given much consideration in the tunnels
below Kandahar.

5698. 2E26 driving an 829B...what is it?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-21 03:23:18 UTC
From: Steve Bauder <sbauder@wwt.net>
Message-ID: <3BAAB2A6.E6B08562@wwt.net>
Source record: 50043

I've been thinking about building a 6146 amp for my 6 meter TenTec transverter. Looking through my junkbox, I found a chassis of a project that is about 90% complete. I have no idea where I got it...I didn't build it! It might just be a 6 meter amp waiting to be finished. I'm looking for help in identifying this project and finding the original plans.

It appears to be a 3 stage transmitter. The oscillator tube is missing, but it's a 9 pin receiving-type tube. There is a switch to select between a crystal or an external VFO (I think). The oscillator feeds a 2E26 with a tuned input. The 2E26 feeds the 829B in push-pull. The output of the 829B is also in push-pull, which is link-coupled to the antenna. The wiring/coils appear to be 6 meter-ish. Certainly not for 2 meters. Vintage appears mid-60's (9 pin tube, small disk caps).

Any ideas?

Thanks,
Steve, nx9z

This was a very common and favorite tube lineup back in the 40's up into
the 50's. Probably a 6-meter rig - you should get some idea from the sizes
of the tuned circuits. Check some old Handbooks of that era.

What ? No. Different grid bias. Except in the case of a CB amplifier where
replacing 250s by 350s is a great idea....

>> Can anyone comfirm whether CW bandwidth does vary with keying speed?

No, it does NOT vary with speed.

The bandwidth varies with the rise and fall time and slope or shape
oif the rise and fall time.

Bandwidth is constant for a constant waveshape, although the peaks in
sidebands can waddle around a bit with speed. The average POWER in the
sidebands (clicks) will vary with speed and what is being sent.

>Now, the actual BW used will depend on the shape of the waveform. If you

>of harmonics since that's what a square wave really is, the fundamental
>plus the odd harmonics. So, keying at 1kHz will give energy at 1kHz,
>3kHz, 5kHz, etc.

No one keys at 1kHz.

We key in the range of hertz, not kilohertz, and that rate varies
between dots and dashes as well as with the speed and what is being
sent.

While the sidebands move all around, the harmonics are spaced so close
that with useful receiver bandwidths we can't sort it all out as
seperate sidebands.

What we hear is unrelated to speed, unless the radio has a flaw that
allows to change the shape of the rise and fall of the waveform.

Slight changes in shape can make large changes in clicks. Most modern
radios are poorly designed, and have poor shaping and excessively
short rise and fall times. Not only that, the radios can change
frequency while being keyed so a good appearing waveform can still
occupy a wide bandwidth. The IC775 is particularly bad at that.

Look at www.W8JI.com under clicks.

I got a letter from the RA today telling me
that 5 WPM is now okay for a full licence.
I can keep my M5 or change it for an M0.
I still get the full privileges if I keep M5.
So they have dropped the CW test
for the full UK licence to 5WPM.
Any other changes any one knows about yet?

Sorry Alan, that is a popular misconception but is not true.

The bandwidth is set by the shape of the rise and fall times of the envelope, and NOT the keying speed (unless of course you take keying speed to zero Hz).

You need a certain SYSTEM bandwidth to accomodate a certain maximum speed under certain conditions of reception (like various conditions of fading or noise for a given speed), but the occupied bandwidth remains the same even if speed is reduced as long as you don't readjust the filters in the transmitter and receiver.

It is absolutly incorrect to say bandwidth is set by keying speed. It is set by the envelope shape, frequency-related characteristics (like a swooping VCO that comes on to frequency while the radio actually has output), ringing in filters (the FT1000D has this problem on transmit, they band the SSB filter with a square wave and the filter rings and causes clicks), and group delay errors in filters.

If I send 2 WPM or 50 WPM, my clicks extend exactly the same amount of bandwidth. They may occur less frequently, but the level and spread is the same.

The only exception is if the shape and/or time of rise and fall in the radio changes, but that would be rare unless you approach the upper limit of keying response time.

========================
Hi Ed, just to tidy up, the Morse modulating waveform is a
squarewave. For reasonably-shaped squarewaves, eg, a string of
dots, it would be nice to include, say, the 6th harmonic of the
fundamental.

Suppose one dot plus the space between two dots lasts 1/20 second,
then, including the 6th harmonic and both AM sidebands, the AM
channel bandwidth is 240 Hz.

I'll leave it for somebody else to work out what words-per-minute
correspond to 20 dots per second.

Hi Reg,

The waveform is not a square wave (a least we all hope it is not), but even if it was the bandwidth would extend to infinity at any keying speed.

It is simply the shape of the rise and fall times that control bandwidth, NOT the off-and-on rate.

I think the confusion is people are considering the CW keying a constant modulation at a repeating interval, which it clearly is not (unless your only intent is to send a string of dots or dashes).

The slope of attenuation of sidebands are controlled by the shape and duration of rise and fall times, NOT by the keying rate. You can have more energy in sidebands sending faster, but the bandwidth is limited by the waveshape during amplitude transistions....not by the rate of the transitions.

In other words, if you have a radio on a quiet band and push and release the key only once, I will hear the click the same distance off your frequency no matter how fast or slow you push the key. That distance depends only on the waveshape, not the keying rate.

Parts for Sale:

NEW .1 uF Poly/Film caps - 10% 250v, new stock, paper tape, nice long leads.
These are not NPO and are made by S&M Components

50 for $3.00
100 for $5.00

Ceramic Disk Caps - 103M (.01uF 20% tolerance) rated at 1kV.

50 for $3.00
100 for $5.00

I have NEW BNC chassis connectors for

25 for $12.40
50 for $21.00
100 for $36.00

I also have:

LM7805C voltage regulators. TO220 case. 5 for $4.50
L7806CV voltage regulators. TO220 case. 5 for $4.50
LM7808CT voltage regulators. TO220 case. 5 for $4.50
LM7812T voltage regulators. TO220 case. 5 for $4.50

Get 5 of each for $16.50

22uF 35v electrolytics - $1.00 and 2 stamps for 100 These caps are on paper tape, NOS (New, but old stock) made by Richey. I have thousands. Oh boy.

2N2222's in METAL TO18 case - 25 for $7.50
2N2222's plastic TO92 case - 50 for $4.00

8.192 Mhz crystals HC49 25 cents each, and a 1st class stamp. (I have 100)

Let me know if you're interested. All prices are post paid to the USA. I will ship to non USA addresses but we need to discuss the shipping charges first.

Thanks - My address on QRZ is good.

5713. I have made a Tayloe receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-21 18:33:30 UTC
From: bpasaric@mac.com
Message-ID: <1f03pq7.10pqbih17ettzuN%bpasaric@mac.com>
Source record: 50060

Following the schematic and instructions in Dan Tayloe's patent documentation, the "Letters to the Editor" in the QEX (Dec. 2000) and the information I picked up in this news-group some three months ago, I managed to make a Tayloe receiver which works. I made it on a perfoboard. The multiplexer is a Fairchild FST3253 (SMD style), the binary counter is a Fairchild 74AC163, (in front of which I put a 74F00 to shape the pulses), the I and Q amplifiers are two TL071's, and the adding amplifier is another TL071 followed by a TL072 - which includes a low pass filter followed by one more amplifier. At the end of the chain there is an "active speaker" - a small computer amplifier which I regularly use instead of headphones. At the front end of the receiverI have put a tunable resonant circuit wound on an iron no-name powder core for 3,5 - 14 MHz, with a variable capacitor 500 pF max., so that I can tune in any of the three bands. The secondary coil is about Z = 50 ohms connected to the multiplexer.

The VFO is a rock-stable DDS 0-60 MHz which I made about a year ago. At its output there is a group of tunable resonant circuits with a switch, which guarantee a clear output signal. It was of a great help to me because I did not have to bother about the VFO and its stability. The AF phase-shift network is the same as Phil Rice, VK3BHR, has described it in his article "SSB by the Fourth Method?" (Amateur Radio, February 1998, page 16).

I did not have any real difficulties putting the receiver together, except some tedious work soldering the SMD-style 3253 MUX - with the help of a magnifying glass and a lot of patience. The binary counter 74AC163 does not have an up/down pin as some other binary counters do. However, when you wish to switch from LSB to USB, you just swap the I and Q leads with each other, and so change the direction of the rotation. It can be done with a DPDT toggle switch. The bias for the 3253 was provided with a 5 kohms trimmer potentiometer connected between the stabilized 5 V supply leads. During the test reception it can be positioned to the best result. Initially it is in the middle.

The AF phase-shift network also works fine so I got the SSB signal immediatelly. The SSB is very clear. If someone needs info how to connect it, here it is: the filter has four inputs (1-4, take any side) and four outputs (5-8, the other side). Numbers 3 and 4 are grounded. Numbers 1 and 2 go to the I and Q channels respectively. Output numbers 5 and 6 are soldered together, as well as numbers 7 and 8. So you get a double 0 - 180 degrees output, which goes to the adding amplifier (with a push-pull input as I call it).

I also tried to disconnect the 90 and 270 degrees capacitors C2 and C4 after the multiplexer (for the negative half-period) and the receiver continued working correctly, although with some less volume.

The receiver must have an excellent AF amplifier, because all the amplification is realized there. Precautions against hum must be taken; long ground leads pick up hum. Everything is true what Dan Tayloe told us about his receiver, selectivity, SSB, dynamics etc. I listen to 3.5 - 7 and 14 MHz bands, which means that the VFO works on 14, 28 and 56 MHz.

"But where is the "catch 22" - I used to ask myself before I built the receiver, because I know from experience that there is always one. Well, when tuning along any band you can hear whistles which are obviously coming from some harmonic interferences. They are generated inside the RX because they can also be heard with the antenna pulled out. It is easy to tell them from the outside signals because it takes one whole turn of the rotary encoder to tune the outside signal to zero - and only one tenth of it to tune the spurious signal to zero sound. The whistles are especially strong on the following VFO frequencies:

For 3,5 MHz: 14052 - 14118 - 14320 kHz.

For 7 MHz: 28039 - 28105 - 28237 - 28370 kHz.

For 14 MHz, CW band only: 56036 - 56049 - 56079 - 56116 - 56136 - 56158 - 56210 - 56316 - 56386 kHz.

I felt very proud when the receiver first worked, but now I am a little worried because so many spurious signals spoil the pleasure of listening. On 3.5 and 7 MHz it could be tolerable, but not on the 14 MHz band. Now, can anyone explain to me the reason for so many spurious frequencies, and can anyone advise me what to do and how to get rid of them?

Many thanks for any help - Bozidar, 9A2HL

Driving a 5894 to 180W RF in class AB on 2m you only need 1W, so I
would believe you don't need more for driving 829B to full ratings on
6m A suitable driver for 2m is 6761 or 6939 although the latter is
somewhat too strong.

Just keep in mind the bandwidth answers were wrong though Ram.

The bandwidth of an AM signal relates to the highest modulation
frequency, and that relates to the SHAPE of the modulating waveform.
Not how OFTEN the modulation occurs when it is off-and -on modulation
like CW.

Hi, Im a swl
and I want to build as high-pass filter for my shortwave receiver (DX-398)
I have it fed witha 75ohm coax .
I want to suppress strong MW stations that create intermod on the
shortwave bands(especially around 2-3 mhz)

So I would like to build a filter that would attenuate the frequencies below
1.7 Mhz
have a input and output 75 ohms

I think I should build a chebyshev , but I dont understand what passband
ripple is. and how it affects the filter performance.
I also see a butterworth and elliptic filters,maybe I should take a look at
those. I need some guidance!

Thanks

The easy answer is to not use a DDS! The detector works fine with either a normal VFO or a VFO that has been mixed to a higher frequency using a crystal osc with no birdies. The nice thing is that many of the ham bands are harmonically related by a power of two, making frequency generation of the lower bands from a higher band relatively easy.

DDSs are kind of dirty as they are really designed for transmitters (certainly clean enough for that) or for cellular phone reception for signals of with limited dynamic range (such as a cellular basestation using power control of all the phones in its area).

I used a pair of AD9851s in quadrature lock to drive one of my receivers and have heard the same you have. The birdies I was getting seemed to occur at regular intervals and were extremely narrow. It lead me to believe that I could use a processor and "skip over" the birdies using frequency "jumps" of much less than 1 Hz.

You could give that a try, but the use of a DDS with numerous in band spurs as high as 80 db down will limit the performance of the receiver. However, a DDS is a nice way to try things out and see how they work. I usually use an HP8640/323 signal generator to tune my receivers until I get everything else ironed out and save the VFO part for last.

Tom, although I lack your technical understanding - this is intuitively what I felt when first reading the Harry Helm book.

Provided you can maintain a constant amplitude/frequency/waveshape continuous wave - then simply keying on/off would create no sidebands in itself and bandwidth will not be directly determined by your keying speed.

In contrast, it is very easy to understand and accept that the CW bandwidth is directly related to the degree of amplitude/frequency/waveshape variation at the beginning and end of the envelope (during the "rise and fall" times).

Many thanks for an interesting thread.

If you turn the question around and ask what would the minimum bandwidth
required to receive a cw signal of say one word a minute vs 35 words a minute,
you would find that the required bandwidth would be much smaller for the one
word rate. This narrow bandwidth could spell the difference between receiving
the message or not as the result of reduced noise resulting from the narrower
bandwidth.

If the keying speed is increased N times so is the signal
bandwidth. Quite obvious !

The sidebands _do_ get wider with increased keying speed. What Tom is saying is that the splatter still goes out as far on each side regardless of the keying speed. It is a function of the keying waveshape.

If we ignore the key-click splatter the actual information is in the main sidebands associated with the keying periods. You can filter out everything beyond them and still preserve the information in the CW signal. IMO that is its 'bandwidth'.

However if you do that, it won't sound very good at all. The edges will be so smudged it will be hard to read by ear. So practical CW transmitters send somewhat clicky signals with much wider signals than just the information sidebands.

The sidebands move out N times the distance, but the 'harmonics' of the
sidebands (caused by the spectral content of the baseband keying signal)
have the same envelope.

This is what Tom was saying.

There is no practial filter in common use that can slice off just the
first dit sideband from a CW transmitter signal. Even if you built a
digital monstrosity that could send minimally keyed CW no human would
enjoy listening to its output.

I still say that the speed of CW determines its 'bandwidth' but that is
largely a semantical argument. Practical CW signals contain _many_
times they keying period bandwidth.

In good quality amps, the simple swap seems to produce less output,
and not more. The 350's are more difficult to cool because of the
higher restriction through the plate radiator. Also, if you are using
your 'boot' at 27 mhz, be sure to ask the F.C.C. if they think the
tube swap is a good idea.

Hello

I have a Amplifier made up with the tube 4cx800.
I have problems with flashover in Plate capacitor, this only happen
on 14 Mhz.
Typical happen when the power increase to about 600 - 700 watt.
This newer happen on the other band eaven with 1 kilo Watt
Plate space is aprox 3 mm.
Someone have any idea.

yup war is hell,so why kill more people,if you kill more people that is
murder,so if its war,then murder is ok,is this is what you are saying.

so if i say i am at war with the guy next door to me,then i go in and kill
him and his family,that ok because i declared war on him.

Bozidar,

How confident are you that you are not picking up harmonics of the logic section of your DDS and/or digital control system? Unless you have extremely good shielding of the logic and also very good filtering of the common power supply voltages, there is a very good possibility that some low frequency component of the fast rise-time logic signals are getting back into the mixer. The Tayloe mixer will respond to input signals at harmonics (mostly odd harmonics in this case) of anything that sneaks into the circuit. In the examples you cited, I did some quick calculations and found some common-denominator low-frequency differences between spur frequencies.

I wouldn't give up on the DDS yet. If additional power supply decoupling and waving of hands over the circuit changes the whistle intensity, then there's a good chance that it's not the DDS...yet. I agree with Dan that the DDS will never be as good as an analog oscillator, but I don't think you've banged into that wall yet.

Please keep us informed. The Tayloe mixer, along with DSP processing of the IQ audio, is great stuff. I'm watching for someone to make a complete and very inexpensive commercial transceiver about the size of a postage card that uses a laptop PC's soundcard for all the IF/audio processing as well as the control interface. I think this will revolutionize Ham radio.

Since there seems to be quite conflicting arguments about this in this thread, I hope I can clarify some things.

First of all, you have to be very careful how you define "bandwidth". It is quite simple to define the bandwidth for SSB and AM as it is the same resp. twice the audio baseband bandwidth. However, the situation is quite different for FM or CW.

In FM, you have theoretically an infinite number of sidebands occupying an infinite bandwidth. However, the amplitude of the higher harmonics are very weak and finally they are masked by noise. How do you define the bandwidth for such emissions ? You simply define an arbitrary level and then you just search for a offset from the carrier at which the sidebands are all below this level. For some modulation methods, this level is set at -26 dB below carrier. In amateur radio regulations the level is usually set at -40 dB (or -60 dB in some cases).

Take an ideal switch, that turns on a DC current for 100 ms and off for 100 ms (e.g. a keyer sending a string of dots at 12 WPM). This produces a square wave with a 5 Hz repetition rate. An ideal square wave consists of only odd harmonics, each having an amplitude of 1/n, where n is the harmonic number. Thus, the 999th harmonic is about 0.001 times the fundamental amplitude or -60 dB down. The 99th is at about -40 dB.

When this waveform is used to key the transmitter, it will actually amplitude modulate it, producing symmetrical sidebands on both sides of the carrier, with the strongest sidebands (fundamental) at +/-5 Hz from the carrier. At +/-500 Hz the response would be -40 dB, at +/-5 kHz -60 dB and at +/- 50 kHz at -80 dB. Thus, the key clicks of a nearby station would be heard all over the band. At larger distances these clicks would be buried in noise. By using the -40 dB point as a definition for bandwidth, the bandwidth would be 1 kHz.

Dropping the keying speed to 5 WPM, the fundamental would be at +/- 2 Hz, the -40 dB point at +/-200 Hz and the -60 dB point at+/-2 kHz. Thus, using the -40 dB definition for bandwidth, it would be 400 Hz.

To avoid this problem, some pre-modulation shaping is applied to the original square wave, i.e. the rise and fall times are stretched.

Usually 5-10 ms rise and fall times are used in amateur gear. What effect does this have on the spectrum ? The location of the sidebands are still determined by the pulse repetition frequency.

However, the amplitude is less than 1/n, especially for the higher harmonics. Thus, fewer harmonics would be above the -40 dB limit and you could say that the bandwidth has been reduced.

I just made some simulations using 12 WPM and 5 ms rise and fall times and the 7th harmonic (+/-35 Hz) was at -3 dB, the 9th (+/-45 Hz) -5 dB, the 11th (+/- 55 Hz) -9 dB below the ideal square wave. at around the 13th harmonic (+/-65 Hz i.e. 130 Hz bandwidth) the response would be about -40 dB, which is used as the definition of the bandwidth in this article.

Thus, the premodulation shaping main effect is reducing the amplitude of the sidebands above 30 Hz.

Using 5 WPM (with a 2 Hz fundamental), looking at +/- 60 Hz, we are talking about the 30th harmonics, in an ideal square wave it would be 30 dB down and assuming that the pre-modulation shaping would still attenuate it by 10 dB, thus the total response would be -40 dB down and thus, the bandwidth would be 120 Hz.

Compare this with the 130 Hz bandwidth for the 12 WPM example.

The old CCIR recommendation state that for aural CW reception, at least the 3rd harmonic of the baseband waveform is required or the 5th if there is a strong fading. Since the 5 ms rise and fall times will produce a bandwidth of 120 - 150 Hz, at 150 Hz the 5th harmonic would be at +/-75 Hz and the fundamental frequency 15 Hz, corresponding to 36 WPM.

Increasing the rise and fall times to 10 ms would limit the usable speed to 18 WPM for fading contacts and 30 WPM for non-fading contacts.

While this discussion has been about a string of dots at 5/12 WPM, this is the worst case and all other combinations in the Morse alphabet will produce lower sideband levels.

The CW bandwidth is a complex thing, first of all, you have to understand how bandwidth is defined and then note that the bandwidth depends on the keying speed, but this relationship is not linear.

Band pass filtering is not usually very efficient, but band stop
(notch) filtering has been used for decades to attenuate unwanted
frequencies. Just get a T-connector and connect a 1/4 open circuit or
1/2 short circuit cable to the side of the T-connector.

To attenuate a 100 MHz signal from your rig and assuming 0.66 coaxial
velocity factor, a 1 m long shorted coaxial cable attached to the
side of a T connector should do the job. You can tune the resonator by
putting a needle through the shield and central connector before
permanently soldering the connection at the far end.

> like CW.

Wrong:

Imagine a continuous string of dots, each having a constant rise time and fall time of
7 milliseconds and a 50% duty cycle. As the dots per second increases the spectrum width of the signal will increase.

Reason:

The spectrum of the continuous string of dots consists of a set of discrete sidebands that are separated in frequency by the repetition rate of the dots. For example, a rate of 10 dots per second produces the first (dominant) pair of sidebands (high side and low side) that are spaced from the carrier frequency by 10 Hz. Subsequent smaller pairs are separated by 30 Hz (3 x 10).

The width of this spectrum is influenced by the 7 millisecond rise and fall times, and also by the dot rate. But if the duration of the dot is much greater that 14 milliseconds
(it almost always is) then the spectrum width is determined almost entirely by the dot rate.

The purpose of the 7 millisecond shaping is to attenuate higher-order sidebands. But if the dot rate increases too much the dot becomes "smeared" in time, which means that not enough sidebands are present. For the string of dots, the first and most important sidebands are plus and minus the dot rate (10 Hz in my example). At excessive dot rate these sidebands (and a few of the other sidebands) may be attenuated too much.

Also, the string of dots is a special kind of low-level amplitude modulation in which the power in the sidebands is derived from the keydown power. For example, 100 W continuous keydown becomes, say 80 watts in the carrier and 20 watts in the sidebands. This is different from ordinary high-level AM in which an amplitude modulator supplies the sideband power.

This analysis also applies, in a more complicated manner, to a random Morse signal. The bandwidth depends on the code speed, assuming that the dot time is much greater than 14 milliseconds. The receiver bandwidth must also be adjusted.

Further material is in chapter 17 of the 1995-2002 ARRL Handbook (written by Sabin).

so miniimum bandwidth for 20WPM is 8.33Hz *3 *2 = 50Hz, suggesting
that the filter must pass at least 3rd harmonic of the repetive keying
frequency of a continious series of dots

Normally, tuning problems and stability of the received signal makes
the limits, I find 100Hz almost minimum in practice using DSP-9

Your intutition is correct. Good job! Many people miss this.

>Provided you can maintain a constant amplitude/frequency/waveshape
>continuous wave - then simply keying on/off would create no sidebands in
>itself and bandwidth will not be directly determined by your keying speed.

That is correct, because it is the rate (time) and shape (slope) of
the rise and fall of the envelope that sets the bandwidth. The
off-and-on signal is so slow, that it's harmonics are unimportant.

Let me give you an specific description.

I can turn a transmitter off and on with what is essentially a square
wave. If we looked at a frozen spectral display captured during the
rise time, it would have certain amplitude distrubution with
frequency. It wouldn't matter if we tuned that signal off-and-on a
million times in a day, or only once a day, the spectrum would be the
same as long as the rise was fast enough to allow a full turn-on
period.

Now the steady-state level has NO bandwidth. It is "DC" modulation. So
once again, how OFTEN we make it appear and disappear doesn't matter.

The fall tme is identical to rise time. It generates sidebands. The
LEVEL of the sidebands are controlled by the delta in voltage, while
the frequency distribution is controlled by the rate of the slope at
any period of the changing level.

Very plainly, when we put this all together, we have a "click" that
extends up and down in frequency that is controlled ONLY by the rise
and fall times and not affected by the keying rate as long as the rate
is possible to achieve.

Where people screw this up, is they assume we have an unfiltered
transmitter with infinite bandwidth capability, that simply allows a
fast steady off-and-on modulation out. In that case a higher
modulating frequency does affect the level of signal off frequency,
and the lowest sideband will be the basic modulating frequency.

What most people forget is that CW is a rise (that IS the modulation),
a period of NO modulation (that is the "key down") and another short
period of modulation in the fall time followed by another period of NO
modulation when the key is up.

The modulating frequency is the RISE and FALL period, NOT how fast you are moving the key! You can move the key one WPM, or 100 WPM, and bandwidth is the same. Only the rate of clicks will change.

Someone else said or implied we can't filter the bandwidth, but that is clearly wrong. The type of filter we use can be applied before the stage is modulated, or it can be in the RF system after modulation. If I use a single R/C filter (a single pole filter) we will have one slope of attenuation of sidebands as we move off frequency. This is the waveform the ARRL shows as an "ideal" waveform...but it is NOT. It was ideal perhaps when we had grid-blocked keying and only wanted to use one resistor and one capacitor to shape the modulation.

The ideal filter would be a multiple pole filter with minimum group delay error with frequency, and a steep rolloff. The result would be a sine-shaped modulation rise and fall that would start at the bottom crest, turn slowly upwards and roll over at the top without overshoot or any abrupt changes in dV/dT at any point in the waveform. We could do that with a multipole op-amp filter having Q=1 in each filter section.

This assumes the modulation is applied in a linear fashon.

Now the time of that slope would set the maximum possible keying rate, but the BANDWIDTH of the signal would be the same no matter how fast we keyed it. The bandwidth, whether we send .001 WPM or 100 wpm is exactly the same, because the modulation frequecy is the RISE and FALL times....not the keying rate. The clicks happen more often or less often with speed, but the bandwidth and peak level of clicks in a given frequency range is set by the shape and duration of the MODULATION, which is only during the rise and fall times.

The interesting thing is apparently most radio manufacturers have no idea how this works, or don't care. We have horrid 1mS and faster rise and fall times on popular rigs, and abrupt changes in slope during the short periods of modulation (the rise or the fall).

If you look at keyclicks on www.w8ji.com, you will see the changes I made in an FT1000D and FT1000MP with changes in the slope and duration of the rise and fall. On a spectrum analyzer, it makes absolutely no difference if I key the rigs at 50 WPM or 5 WPM, the nadwidth is indentical.

I hope this helps. I sure hate to see so many wrong descriptions of a simple process!!

Very good Paul!

Perhaps you can visit the big amateur manufacturers and show them how to build rigs that do not click for 5kHz (whether sending at one or one hundred WPM) .

Because the keying speeds are at Hz, and the filters we listen with are in hundreds of hertz of bandwidth, we care less if the little sidebands move around from keying speed. We certainly do care if the sidebands extend far beyond the bandwidth of the narrowest filters we are typically using!!

The real modulation frequency we are concerned with are rise and fall periods, not how often they randomly average a certain repetition.

Hi Rune,

There can be a few causes, but they all relate to the peak voltage
exceeding the voltage braekdown of the capacitor.

Common problems are:

1.) Improper loading, with too much capacitance on the loading
capacitor for the peak power.

2.) Poor relay timing. The input relay is closed when the output relay
contacts are not closed or are bouncing.

3.) An arc or momentary open or short in the antenna or feedline
system, such as in a lightning arrestor (very common) or loose
connection.

4.) An exciter transient. many exciters spike on power. Are you
running your exciter near the full power (that is best), or do you
have it turned down? (That is bad, if you are running the exciter at
low power you probably need to attenuate the drive some other way).

5.) A brief oscillation AT or NEAR the resonant frequency of the tank
circuit. (Not at VHF, as some people wrongly assume).

I assume you looked at the air variable and the plates are aligned
properly, and there are

Anyone have guidance for modifying a Messenger M4V or Super Star 200
CB (10 meter, yeah right) amplifier for 80-10m use?

I have a FT-817 and it needs some help when conditions are right or
when
mobile on an inefficient antenna. These amps are designed for low
drive.

I saw a couple of reasonably priced amps at a recent Ham flea and
thought
they might be the answer within my budget. The Messenger M4V was $75.
asking, the Super Star 200 $125. asking but I'd guess will sell for
$75. or so.

I am aware that I will need to add a switched filter system to the
output and
that the input on 80 and 40 will probably require a 18 ohm input
resistor to
raise the impedance.

Thanks! & 73, Doc KD4E

That is simply not true. If you key on/off at a rate of x/second, then a spectral component of x hz will appear in the output. That
component is independent of rise/fall times or shapes. Go back to your DC example and think it through again; you will have
the spectral components of the key clicks, as you say, which are independent of they keying speed. You will also have a
spectral component equal to the keying rate, which is independent of the key clicks.

Hi,
Here's a web-based filter design program that's easy to use, and will design a filter for your needs.
http://www.wa4dsy.net/filter/hp_lp_filter.html
Normally you'd use a 0.1dB ripple Chebyshev filter. Buttorworth won't give a steep-enough attenuation; elliptic designs require tuning the null elements. Chebyshev filters, at BCB frequencies, you can simply solder the components in and use the filter; no tweaking required, generally. You usually want low ripple, plus a 0.1dB design doesn't require high-Q inductors, like higher-ripple designs do. Use Amidon iron-powder toroids for the inductors. Use mica capacitors, NPO disk ceramics, or other high-quality capacitors. A 7 or 9-element filter should be sufficient. You'll need some way of measuring inductance, and probably capacitance, to make a homebrew filter. Build it on a scrap piece of PC board. For a highpass filter, use the inductors as tiepoints for the capacitors, since one end of each inductor goes to ground/common. Use the highest frequency you can for the cutoff frequency, e.g. if your interests are above 3MHz, use 2.5 or 3MHz as the filter cutoff frequency. That will give the most attenuation for BCB frequencies.
Enclose in a well-shielded box; a diecast box is ideal. You could use common F connectors on the enclosure and for the coax cable. There's no reason to design the filter for 75 ohms, even if you use 75 ohm cable, but it won't hurt, either. Most filters are designed for 50 ohms. For receiving applications below 30 MHz, there's absolutely no difference in using 50 ohm or 75 ohm cable. 50 ohm is the industry-standard for most everything except CATV and video. Your radio has a nominal 50 ohm external antenna impedance.
Email me off-list if you have any other questions. I've been building filters for many years both for hobby and for work.
Any ARRL Handbook in the past 10 years or so has tables for scaling filter designs using Standard Value Capacitors for any frequency you'd like. That eases the capacitor selection since you can just use standard capacitor values rather than paralleling several caps to get a non-standard value, such as the above filter design program uses. I make my filters with exact-value designs since I can measure both caps and inductors. Performance is better with exact-value designs, too.

Hi,

One way to get rid of the DDS spurs is to only use outputs that "fit" inside the range of your output DAC. In other words if you have a 14 bit dac and a 32 bit DDS use outputs that are at clock/N where the 32-14 = 18 lsb's of N are all zero. Unfortunately this restricts you to fairly large steps on your DDS. Something like 1800 hertz or so at 14 MHz. That kind of makes it a hard technique to use for receivers.

You can fiddle around with sub hertz steps and at least spread out the energy a little but the only real major reduction is when you hit an output that is a DAC sized number.

The other way to do it is to clean up the DDS by phase locking a VCO or VCXO to it's output. You can also buy modules that will do that for you.

Enjoy!

Bob Camp
KB8TQ

Truth in advertising note - yes we do make the clean up modules ....

Sorry, but that is true. The off-and-on frequency is slow compared to
the rise and fall times. So while that component does appear, it does
not affect the overall bandwidth.

As the clicks appear more frequently with higher speeds, the
time-averaged amplitude can increase but actual bandwidth is set by
the shape and rate of the rise and fall...since that is the ONLY time
the carrier is changing level.

Since QRM is a sort term affect, we will have QRM the same distance
from an unfiltered or improperly filtered waveshape regardless of
speed.

I've been using that AD9851 for a few years, and have noticed that it is not the cleanest LO around. I found that by placing a 4.7uF tantalum cap right at the PLL Vcc pin, many of those spurs are reduced quite a bit. Still, the spurs don't seem to get lower than -80dBc, with some of those in-band ones at -54dBc. I get around this problem by using 1KHz tuning steps, and having variable BFO injection into the Product Detector.

This is simply not true, please read my previous posting more
carefully, in which I stated

1) The _location_ (frequency) of the sidebands depends of the keying
rate
2) The _amplitude_ of these sidebands depends of the wave shape
3) The bandwidth depends of the reference level used.

Using an unfiltered string of dots at 24 WPM will produce harmonics
for every 10 Hz offset from the carrier, of which the odd harmonics
are of any significance. At an offset of 10 kHz, we are talking about
the 1000th harmonics, which is about -60 dB down.

At 5 WPM, the fundamental is at 2 Hz, thus at 10 kHz, we are talking
about the 5000th harmonics, which is -74 dB down from the carrier.

The premodulation shaping will reduce these levels even further, but
since the 5 WPM started at 14 dB lower levels, the difference in
sideband amplitudes still remains after filtering. Using a fixed
reference level for bandwidth, the slow CW will have a slightly
narrower bandwidth. However, the difference in bandwidth is much
smaller than the ratio between the keying rates.

That is correct. We need to set the rise and fall to accomodate the
fastest speed, and the worse conditions of fading.

But where we disagree is in the rate of CW affecting bandwidth once
the rise and fall and the shape of the rise and fall are set.

In that case, as I clearly pointed out, only the POWER in the
sidebands changes. The bandwidth does not.

>Further material is in chapter 17 of the 1995-2002 ARRL Handbook (written by

>
>Bill W0IYH

Quoting yourself as a reference does not mean much, because I would
hope you already agree with yourself.

Reference Data for Radio Engineers in the section on radio noise and
interference describes adjacent channel interference problems with CW.

The Sixth edition on page 29-10 and 29-11 clearly shows that bandwidth
of each dot (or dash) is set only by the rise and fall shape and
duration. This bandwidth (where our ears would perceive a "click") is
always much wider than the sidebands of the actual keying speed.

It is also constant, so the click extends out in bandwidth exactly the
same distance each side of the carrier if you send one dot a year or
one dot a millisecond, assuming the dots (or dashes) are longer than
the rise and fall times.

The only thing that changes with dot speed is the power in that
bandwidth.

I certainly agree that if you send 60 wpm the clicks are more
disruptive than if you send at 1 WPM (because average power is
higher), but as far as how far off frequency the sidebands
extend...that is controilled only by the slope and time of the rise
and fall.

I can clearly see this on a spectrum analyzer using say a 100 sweep average of peaks. The bandwidth trace remains exactly the same no matter what dot speed I run, as long as the dots are longer than the rise and fall times.

I know that because I just did this test on several rigs as I looked at waveshape.

Perhaps Reference Data for Radio Engineers is wrong, and my spectrum analyzer is broken. I'll check on both and let you know.

Too bad they do not include that in Handbooks Jan.

Keyclicks are becoming a major problem now. I hope the ARRL starts to measure the spectrum of CW transmitters instead of the almost useless pictures of the envelope.

I was experimenting with a raised sine waveform filter all in one chip, but unfortunately it does not go low enough in frequency to be useful for CW (and has too much ripple on the output).

I wound up using a quad op-amp with Q=1 lowpass filters set for 150 Hz driving a PIN diode modulator. I'll use that in my homebrew rig, rather than the terrible shape of a simple R/C filter.

My other choice was to use a CW filter in the transmitter IF after the keying, and linear stages after the filter.

Improper L/C ratio can not cause it, unless the tank is underloaded
allowing the tube to "ring" the tank which can cause peak tank voltage
to exceed twice the dc supply rail by quite a margin.

Parasitics near or below the actual operating frequency can cause it,
but they are probably very rare and he would be getting other
complaints...hi hi.

These amplifiers are very poorly designed. They not only lack proper harmonic filters, they are actually class C.

I measured a "Super Star" for a ham, and it was about -18dB 3rd order IMD with significant level on products extending out to the 15th order product. That would make you the undesired center of attention on any low background noise band when your signal levels are reasonably strong.

You would have to bias them into conduction with a stiff stable bias source, as well as fix some impedance issues in the transformers and add filters.

Best to stay away from non-type accepted "stuff" built for CBers.

You are wrong about that. Any CW operator knows that fast code requires more bandwidth and that very slow CW uses very narrow bandwidth for micropower communication. Anyone who understands signal processing mathematics also knows it. I understand signal processing mathenmatics and I know it.

I think that two things are being argued here.

Tom says that the *transmitted* bandwidth
is invarient. In a certain sense, that is true.

The original question (I believe) was what
minimum bandwidth would be required to
successfully receive a given cw speed.

My 51 years as a ham (and 38 years as an
EE) have convinced me that you need a
wider bandwidth to copy 50 WPM than
1 WPM. I may be wrong, but I don't think so.

Nonetheless, it is comforting to have someone
so confidently omniscient in our newsgroup.

Let me correct the error myself, Omagh is in County Tyrone not County
Londonderry. Thinking too much and typing just as fast.

Wouldn't it just be easier to store the keying waveshape in a EPROM and use that to modulate the low level RF stages, before the linear output bits? With the EPROM you can have all sorts of wave shapes in there for different speeds and QSB conditions.

Seems easier than huge synthetic inductors at baseband frequencies. Alternatively you could use a crystal filter in the TX chain to limit the keying crap, then you could key with a square wave if you wanted to.

You can't go overboard with minimal keying though, if you make the dits and dahs Nyquist pulses they are going to be just about impossible for a human to listen to at high keying speeds. Although the key clicks will be gone.

It would seem that some people are talking about the bandwidth required
to receive a signal and some are talking about the bandwidth generated
by the transmission.

If one is talking about the transmitter bandwidth, clearly a square wave
modulation produces a much wider bandwidth than a signal with a slow
rise time. As long as the rise time remains short compared to the period
of the code elements, the harmonics generated by the fast rise time will
set the maximum bandwidth of the _transmitted_ signal.

On the other hand, if one is talking about the _receiver_ bandwidth
required to resolve the signal, that is dominated by the speed of the
code, since the harmonics generated by the fast rise time can be
attenuated without affecting the ability to resolve the information. In
this case, the faster the code, the wider the minimum bandwidth required
to resolve the signal.

Seems to me that you may choose a too complicated solution, this is of course your own business, but not necessary. A problem for the conventional transceiver transmitting CW as described by Leif SM5BSZ is that the keyline has not proper voltage swing for the different stages keyed, one stage may be cutoff while another has some amplification

*) The first rule for good keying is matching key-voltage swing for the different stages, only when this is done one should think about time constants, only then any filter, simple or elaborate, will improve key click.

*) Using a small signal device below 15-20MHz it is perfectly OK to key only one stage, but the RF input level shouldn't be too high, 50dB key on/off ratio is easy to achieve, but YAESU and other tend to use general purpose devices, they will leak some RF and on/off ratio of 10-20dB is often the result

*) Too often keyed stages are overdriven, or the input level increases as the device is shut down, so some RF input level matching is also needed to avoid this. Another problem is that the keyed stage loads the previous stage too much, a simple buffer may improve on this.

For Yaesu FT-221: First keyed stage is an emitter follower after the xtal oscillator, the drive level was reduced to this stage, this also improved the xtal frequency shift for CW-keying. The second stage was IF amplifier, this was replaced using BF199 (I am not familiar with US small signal devices). Then emitter voltage DC-swing was corrected

Hello,

PC 900 is a B7G base triode with a heater of 3.9V 0.3A, Va is 135V
Vg -1V Ia=11mA Wa 2.2W Ik=20mA max, u=76 and the gm is 14.5mA/V
A very promising valve to experiment with in low-level stages, both
audio and HF/VHF amplification. It was developed for use in VHF and
UHF television tuners.
I have 400 pcs in stock and the price is only $ 3.00 each or $ 1.50
each if you buy 100 pcs or more. The valves are NOS, in mint
condition, original boxes and the label is Haltron, but they are
rebranded, and I think the are originally made by Philips or Siemens.
E-mail me if interested.

Best regards,

Arnold Goksyr

DEMOSTENES - N6899 Balestrand, Norway

well, you may say that for transmitting a signal with certain very
small rise time need a large bandwidth -whatever the keying speed is,
while some rise time is needed to avoid a certain degree of key
clicks. Then the techniques outlined by Paul applies

Unfortunately the manufacturers don't seem to care too much for
avoiding key-clicks, particularly not for VHF, and when somebody
modify their equipment for higher MS speeds by removing the
timeconstant in the keying circuit makes it no good

Integrate that into an automatic keyer, which knows if a dit or dah is
to be generated with possibly different pulse shapes, this will give
the opportunity to generate even cleaner signals.

BTW, with only a DC bias, the fundamental, 3rd and 5th harmonics
present, quite nice looking square waves (strings of dots) can be
generated to feed an amplitude modulator to produce CW. There are of
course some ripple at the top and bottom of the waveform. The ripple
(about 1 dB) on the top half (during mark) is not harmful. However,
ripple at the bottom (during space) is more harmful, since this would
produce some leakage (about -25 dB) during the space period, so some
extra shaping would be needed, which slightly increased harmonic
levels.

As it happens YES.....!

I saw a guy a few years back with the above at a military vehicle show
in Yorkshire, he got it in Eastern Europe somewhere.

And yes Anchor do, or at least did ,have a missile for sale.

But Paul you must get a grip.

Do you really think that the MOD said to old Milosovic (or whatever his
name is)

" Go on old boy knock the !!! out of Kosovo so we can go in and have
ago at you and use up all of our weapons"

And he replied.

"Certainly old chum, I,ll do that. Then you can knock the !!! out of us
and then you can arrest me on war charges"

Duh..

From my point of view the RF behaviors of those components are not the same.
The ceramic capacitors, even for a 0.1 µF value are more RF oriented. Their
impedance are lower in the RF region. In the other hand, the electrolytic
capacitors are the good choice in the AF region.

In the audio section of your rig, maybe there is a need of some decoupling
against RF signals of the vicinity.

Tom---

> The only thing that changes with dot speed is the power in that
> bandwidth.

Not correct.

Think about this: When you insert a 100KHz sinewave carrier and a 2KHz sinewave modulating signal into an unbalanced mixer, you wind up with discrete mixer output products at 102KHz, 100KHz, 98KHz, and 2KHz. The power output of each component varies depending upon the modulation index. In order to resolve this signal, you MUST have an RX bandwidth of at LEAST 4KHz, centered at 100KHz, to demodulate the signal.

Now, let us assume for a moment that you have a perfect squarewave, and you use that same squarewave at 100Hz to modulate the 100KHz carrier. You will have discrete mixer output products at 100KHz, 100+(0.1+2n)KHz, 100-(0.1+2n)KHz, and (0.1+2n)KHz, where n is zero or any positive integer. Again, the power in each of these outputs will depend on the modulation index, and the strength of the individual harmonics ((0.1+2n)KHz) in the squarewave.

Take this line of reasoning a bit further. If we decrease the modulating signal frequency to, say, 50Hz, the sideband term becomes (0.05+2n)KHz. Increase it to, say, 200Hz, and it becomes (0.2+2n)KHz.

THIS TERM DIRECTLY RELATES TO KEYING SPEED. As you can see, if we have a 50% duty cycle string of dits, the first-order sidebands of a CW signal can be found at (+/-x)Hz from the carrier frequency, where x is the keying rate in dits/sec, or Hz. By smoothing out the rise and fall times, we simply attenuate some of the higher harmonics transmitted, giving us better spectral purity. At the reciever end, however, the filter bandwidth required to demodulate and comprehend a CW signal is proportional to the keying speed.

It's simple arithmetic.

Hope it helps,

Henry C. Gernhardt, III
KE4PIB

One factor might be that for very low level signals, ceramics are
microphonic. However, this consideration might be more applicable to
the first few audio stages of a DC receiver than the
last few stages of a commercial superhet receiver.

I assume you mean

100KHz, 100+(0.1*(2n+1))KHz, 100-(0.1*(2n+1))KHz, and (0.1*(2n+1))KHz,

>Again, the power in each of these outputs will depend on the

>((0.1+2n)KHz) in the squarewave.

And here it should be

((0.1*(2n+1)kHz)

The relative amplitudes for these harmonics can be calculated using
the formula 1/(2n+1). Since the carrier is amplitude modulated with
the square wave to 100 %, so you can also calculate the amplitudes of
the sidebands relative to the (unmodulated) carrier level.

yes i know,thats why i stated it,to get in one had no choice,but,i joined an organisation.only the Royal Observer Corps to gain information for CND during the cold war,i state that that,as there is no proof that i did and i could be lying,so any MOD police on this group[IE Dave Mckay] then you will not find proof as i covered my tracks,admission is not enough,so i am reasonably safe.

at the end of the day the stuff i learnt was already known to CND anyway,so wheres the problem??

as usual ranting on

Another way of looking at it - Imagine a very high Q circuit. Send a dot to it. The higher the Q, i.e., the smaller the band-width, the longer it will take for the output to reach full amplitude and the longer it will take to die away.
There will be a speed at which the rise and fall times are too long to make the signal intelligible.
G.H.Ireland, G3CCL

haha- I tried that once and got the same results. "Audiophile"
components don't necessarily have RF field as part of their design and
the bypassing, etc. simply isn't up to par in such an application. All
is not lost because if you get out your the wallet there are some
'transmitting capable' equalizers out there.
A good mike, or voice lessons may be cheaper-eaper-eaper-eaper. Excuse
me, let me cut off the reverb. Beep.

J M Noeding wrote in message <3badea8f.624924771@news.online.no>...

>>The original question (I believe) was what
>>minimum bandwidth would be required to
>>successfully receive a given cw speed.
>>

My original question was to challenge a statement in the book I had been reading (ISBN 1-878707-04-3) where the author argued that because of the general principle that "the more information you put into a carrier the greater the bandwidth always becomes" it followed that the energy spectrum occupied by a transmitted CW signal was directly determined by the keying speed.

START OF QUOTE (page 98)

An unmodulated carrier occupies very little frequency space, but if we send Morse code by interrupting the carrier, we slightly increase the bandwidth of the signal. The usual rule of thumb is that the bandwidth of a CW signal can be found by multiplying the speed in words per minute (WPM) by 4. A signal of 20 WPM will occupy about 80Hz, while a 30 WPM CW signal will occupy 120Hz of bandwidth. The extra band-width occupied by the faster code speed reflects the additional amount of intelligence present in the faster code speed (that is, more information is being transmitted in a given amount of time). The same thing happens with RTTY and digital signals; the faster information is transmitted (the higher the "baud rate"), the more bandwidth such signals will occupy.

END OF QUOTE

I had a feeling that something might be wrong so I asked the group for confirmation.

In the digital signal processing that I have worked on in the past (mostly serial communications) the problem was more one of preserving the pulse waveshape as higher harmonics became attentuated at higher transmission speeds - and I was doubtful whether even the somewhat simplistic argument 'more information means more bandwidth' was meaningful at the low keying frequencies we use to key CW.

Some people posted or EMailed saying that CW keying was just like AM modulating a carrier with a squarewave - implying that the CW bandwidth is relative to the highest keying frequency multiplied by a coefficient to compensate for the waveshape being square. As a result, the faster you key, the broader the bandwidth.

I still have problems with this analogy. Just because 0 and 1 are numbers does not mean that every model for processing analog variables will necessarily be meaningful in real-world terms for discrete variables too.

Is it not true to say that the 'sidebands' caused by on/off keying of the carrier itself are simply the result of the presence or absence of the signal in the time domain - while the spectral spread caused at the beginning and end of the envelope during rise and fall times is the result of variations in amplitude/waveshape of what is (during the mark period itself) a continuous signal.

I feel no resistance to the concept that CW bandwidth might be determined more by the variations in amplitude and waveshape during rise/fall times and if (as Tom is arguing) these rise/fall times are dependent on other factors such as rig design then I would have no problem accepting that CW bandwidth is not determined by keying speed itself.

Thanks to all contributors. I am learning a lot from this thread.

Well, you are using it wrongly. The rane eq was designed for line level input, not mike level. So all impedances and levels are so mismatched you have created a nightmare. You would then have to attenuate the line level output of the rane back down to mike level for the rig.

So much wrong, so little time 73

Oh yes, while you're at it, remember that the radio has audio shaping
in the mike circuit, and the rf/if filters shape the sidebands, so all
that you do with an eq is probably screw up everything and sound like
total crap.

5797. balanced mixer question

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3BAEF6C5.1AFA4109@eznec.com>
Source record: 49995

Let's put some numbers on the situation.

If you look at the spectrum of a square wave, it consists of an infinite number of individual spectral lines at discrete frequencies. The first line is at zero frequency if there's a DC component to the waveform. If it's a perfectly square wave, that is, exactly 50% duty cycle, there won't be any even harmonics, just spectral lines at odd harmonics. For example, if the period of the square wave is 1 s (a fundamental frequency of 1 Hz), there'll be a spectral line at 1 Hz, 3 Hz, 5 Hz, and so forth. The amplitudes of the spectral components follow a sin(x)/x envelope, but for a perfect square wave there's only one spectral line per lobe of the sin(x)/x envelope. The net result for a square wave with instantaneous rise and fall times is that the third harmonic line (the one at 3 Hz for the 1 s period square wave) is 1/3 the amplitude of the first harmonic line. The 5th harmonic line is 1/5 the amplitude of the first harmonic line, and so forth. This is true regardless of the square wave frequency.

Now let's compare the spectrum of a 1 Hz square wave (1 s period) with a 10 Hz square wave (0.1 s period). The 1 Hz square wave has the following components, normalized to the amplitude of the first harmonic:

Freq Hz Ampl rel to 1st harmon

1 1
3 1/3
5 1/5
7 1/7
9 1/9

. . . .

and the 10 Hz wave:

Freq Hz Ampl rel to 1st harmon

10 1
30 1/3
50 1/5
70 1/7
90 1/9

Both have an infinite number of components, but in practical terms, bandwidth is always defined as the width of the signal at some amplitude level. Ultimately, the spectral components will drop below the noise at some point. Beyond that frequency, the components are zero for any practical purpose. Let's look, for example, at the bandwidth occupied by

the signal with components at least 1/9 the fundamental. That is, the bandwidth beyond which the spectral components are down by more than 19 dB.

For the 1 Hz square wave, the 19 dB bandwidth is 9 Hz. For the 10 Hz square wave, the 19 dB bandwidth is 90 Hz. Choose any signal level you want, and you'll find that the bandwidth is directly proportional to the fundamental frequency of the square wave (or inversely proportional to its period). So if the rise and fall times aren't limited, the bandwidth is directly proportional to keying speed. Incidentally, the amplitudes of the various components aren't affected at all by the speed. If you amplitude modulate a carrier with this square wave, you'll have the same spectrum, but shifted up to the carrier frequency, and with a mirror image on the lower side of the carrier also. The bandwidth of this signal will be twice the bandwidth we're calculating.

Now, what happens when we limit the rise and fall times of the square wave?

The simplest form of shaping is done by running the square wave through a single pole filter, such as a series R/shunt C lowpass circuit. The frequency response of this circuit, when viewed on a log-log amplitude vs frequency plot, is approximately a straight horizontal line up to a "break point", often denoted f0. Above that frequency, the amplitude drops following another straight line at 1/f, or 6 dB per octave, or 20 dB per decade. f0 is 1/(2*pi*R*C). The rise of fall time of the filtered square wave is about 2.2*R*C. To find the overall spectrum of a square wave with limited rise and fall times, all we have to do is multiply the original square wave spectrum by the response of the filter. For example, suppose we use an RC filter with R*C = 4.5 ms. Then the rise and fall times of the square wave will be 10 ms. f0 = 35 Hz. Up to 35 Hz, the attenuation of the filter will be minimal. (Actually, it's 3 dB at 35 Hz and less at lower frequencies. Although it's not difficult to calculate the attenuation exactly, the "Bode plot" with the two straight lines is easier to visualize. The Bode plot is off by only about 1 dB at twice and half f0, and it's off by less at frequencies farther from f0.) So the filter won't make much difference to any component below 35 Hz. Components above that will drop off more rapidly than they would without the filter. If we run the 1 Hz square wave through the filter, that is, we limit its rise and fall times to 10 ms, there won't be any appreciable difference in the spectral components below the 35th harmonic, where the amplitude is down 20*log(1/35) = -31 dB anyway. Above that point, the harmonics will drop more rapidly than before, but likely not enough to make any real difference. For example, the 71st harmonic will be down 20*log(71) = 37 dB without the filter, and an additional 20*log(71/35) = 6.1 dB with it. It won't be until around the 350th harmonic that the filter will attenuate the spectral components by 20 dB. The effect of the filter will be more pronounced on the 10 Hz square wave. For that one, it'll start kicking in at around the third harmonic. The filter will reduce the seventh harmonic by about 20*log(70/35) = 6 dB. (I skipped the fifth because the Bode

approximation will be noticeably off that close to f0.) The 35th harmonic at 350 Hz, or 10*f0, will be attenuated 20 dB due to the filter. So it'll be down 51 dB with the filter vs 31 dB without. The bandwidth of the 10 Hz square wave will still be greater than the 1 Hz wave, but not by as much -- particularly if you define the bandwidth as being, say, the 50 dB down points.

The bottom line is that the bandwidth DOES increase with keying speed. However, if the rise and fall times are limited to a fixed value for all speeds, the bandwidth won't necessarily increase in direct proportion to the keying speed. The amount the bandwidth will increase when you increase keying speed depends on the risetime-limiting filter frequency and at how many dB down you define the bandwidth to be. An additional factor is the filter response. Higher order filters can be used, and they'll have a sharper frequency rolloff, further modifying the bandwidth.

If you'd like to calculate the rolloff of a single pole filter exactly, the response in dB is 20*log(1/sqrt((f/f0)^2 + 1)).

Nothing new in that.

I knew of the close down of certain Radar control centres , in favour of
Neatishead , a couple of years before it was announced.
The studies,made by civilian companies ,always get leaked out.

these things are always planned/decided a long time before the press
ever know.

I wondered why a small bomb store was built at Mildenhall.
Then a long while after, it was announced Alconbury would close and the
USAF SOS units move to Mildenhall.
They new long before the announcement was made.

I have to say that if your "contacts" are a a "very high level" then I
despair at out national security as it looks like you are ready to pass
it all on.
You admit that you do not believe in the "Official Secrets Act" and then
they pass all this stuff on to you.

Frightening.

Keith

I agree with your power assessment. I've said all along the average power changes. The overall bandwidth does not.

Here is what I am saying.

Imagine a single dot. The rise time of the envelope creates sidebands, which extend out depending on the shape and duration of the rise time. The same is true as the signal falls.

The ONLY time sidebands are generated is during the rise and fall. Neither the on duration or the off duration generates any sidebands.

When we send CW, we increase how often the sidebands generated by the waveshape appear. This changes the time-averaged power in the sidebands, but it does not change the bandwidth.

The effect is the averaged power in the sidebands increases with increasing speed (just as a pulse transmitters average power increases with increased pulse repetition rate) but the bandwidth is the same for one pulse or a thousand. Duration of a pulse does not affect the high order sidebands cause by the rise and fall of the pulse, because it is at such a low frequency.

Maybe we are saying the same thing, in different words.

In the real world, the distance your keyclicks extend and the strength of those clicks on a peak detecting system like a receiver AGC is mainly controlled by the rise and fall times and shape of the signal rather than speed within normal ranges of speed and rise and fall times. The power in the clicks increases with increased speed, but the frequency limit is the same and is set by the rise and fall waveshape.

If a transmitter has a square rise and fall time, it will have clicks for a wide bandwidth even if you send 2 WPM. If it has a rise and fall waveshape like a squarewave sent through a 150 Hz sharp-cutoff filter, that is how far the sidebands will extend no matter how fast you push the key.

Of course the more often you push the key in a given time, the more average power you will have in the sidebands.

Apples and oranges.

We are talking about off-and-on modulation speeds of a few Hz to a few
dozen Hz.

The problem is at hundreds of hertz away.

The modulation you describe is applied with a rise time and fall time
that is a sine-wave following the modulation frequency.

The CW signal is a square wave filtered either before or after
modulating the RF signal.

There is no difference which way we do it, assuming the circuitry is
correct.

You can consider each rise and each fall to be the modulation
frequency that causes the problems. We can make it occur more often
and increase the average power, but each rise and fall has the same
spectrum shape.

Well then, just to be equally pedantic, since we can never generate a perfect sine, there will always be higher order harmonics extending infinitely.

Apples and pears. The problem is infinitely larger than the few hundreds of Hz you're talking about.

Hmmm, reread what I wrote. How far down the military terrorist structure do you go after Bin Laden? His generals, lieutenants, ground pounders, intelligent people, his information curriers that transport a computer zip disk with info, his financial people? All of those people (eyes, ears, brains of the group) have assisted in the WTC and other activities. Some of them probably couldn't fire a weapon. Do you let them go or include them in the war? My post suggest that people who stand around and refuse to lay down their weapons and cooperatate are part of the passive and maybe not so passive group of BL. They play an important part in shielding BL. . In this case, they are a defensive tool that BL is banking on. If the people elect to not be a human shield and not be a part of BL terrorist machine, then don't include them in the war or murder them.

>
> so if i say i am at war with the guy next door to me,then i go in and kill
> him and his family,that ok because i declared war on him.

Not Ok if your neighbor didn't do a horrific act against you. If you declare war (for whatever reason for this discussion) in advance and your neighbor knows it and is able to prepare for it, then that isn't necessarily good either, but better.

War is an ultimate discipline action against someone(s) to make them cease whatever they are doing, wishfully, forever. Typically very costly and a last resort option, but an option. You better not start a war with your neighbor unless you have some military advantage, or you feel suicidal. Now what do you think when your neighbor continually hides behind its spouse, children and pets but causes horrific crime? BTW, the spouse and children freely support the terrorist. Are they still innocent? If you want to continually take in coming from your neighbor and elect to do whatever, of which nothing is an option, then that is your choice. If your neighbor then spreads their hate, death and distructive crime to other people, are you now part of it because you didn't do anything to prevent it?

There is a fine line between an innocent by stander and a trooper and can be very difficult to distinguish between the two.

I've been involved in the design of precision audio-range signal analysis equipment for quite a while now, and especially the analog "front end" sections. FWIW, I've had occasion to make quantitative measurements of some things like dielectric absorption, leakage, distortion, stability and noise, in various types of capacitor. AFAIK, ceramics are better performing, cheaper and smaller than electrolytics in an 0.1uF size, in all respects. There are three reasons that come immediately to my mind for going to a polyester (or even better, polypropylene) film cap: lower distortion (only an issue when there are significant voltage changes across the cap...near filter corner freqs for instance), lower noise at _very_ low frequencies (~1Hz) in certain very special situations when there's DC across the cap, and lower dielectric absorption. I have not seen microphonics to be an issue with modern multi-layer ceramics, though if it's in a place where people will be beating it with a hammer, you might care about that. So...I'd say you just may have found a case of "bad design." (They abound...just because something comes from a company with a well-respected name doesn't mean everything in it is perfect.)

Cheers,
Tom

Hi

Old KW equipment uses the Kokusai MF-455-|OCK mechanical filter Problem: they become "lossy" during time. Apparantly, the actual mechanical filter housing inside the outer filter can, is set in foam and the foam goes gooy. Well, I would NOT have thought that that itself affected much, just the mechanical shock resistance of the filter. So, maybe the foam going splodgy isn't why the filter goes lossy, so that leaves the transducers. Does anyone know if it is the transducers that go faulty? All this seems odd to me, I would have thought a filter would last indefinitely, but apparantly not so. Thanks.

Including tantalums? I was under the impression that tantalums are very
low-leakage caps.

> boot? Is this recomended...

While the 4CX350 is the same physical size as the 4CX250, it
is not electrically the same. The 4CX350 is only suitable for
linear operation (zero control grid dissipation). Also, it
requires 110 volts on the filament, and -220 volts on the
suppressor grid.

Unlike the 4CX250, it needs no cooling air. This can
make it a lot easier to use.

I was in touch with JF1VHX when I restored a Trio JR-310 from 1968 and he confirmed what you were saying concerning the Kokusai mechanical filters and aging. Perhaps he can also explain why?

Date: Mon, 2 Apr 2001 08:58:49 +0900
From: Takaomi Eda <te21c@dh.catv.ne.jp>
Subject: Re: Question about Trio JR-310

Thank you for visiting my web site. The narrow filter intended for JR-310 was MF-455 10AZ, a mechanical filter made by Kokusai Electric. Co. New or Used, 10AZ is very hard to find now, and if you should find one, it would be very likely to have deteriorated. Kokusai's mechanical filters are well known to lose their original performance over a long period of time.

de JF1VHX, Taka.

His web page can be found by following my link below and go to Vitnage Radios and Trio JR-310.

Regards,

Sverre

Hello,

I just got a large stock of valves from an old radio/TV repair shop
that has been closed for years. The owner just died and the shop was
sold at an action.
All the valves are completely new, never used. They are in original
boxes and in mint shape. The valves are mostly HALTRON brand, but
obviously a large part of them are just rebranded by Haltron.

The following are for sale.

950 pcs DY 87 $ 0,40 HV single rectifier

60 pcs EB 91 $ 0,50 = 6AL5
40 pcs EF 50 $ 0,40 WW2 wideband pentode
20 pcs EF 55 $ 0,50 WW2 wideband radar pentode
200 pcs EF 183 $ 0,50 = 6EH7 remote cutoff pebtode
40 pcs EY 81 $ 0,40 Booster diode 550V 150mA
40 pcs EY 86 $ 0,40 HV single rectifier

220 pcs PABC 80 $ 0,50 triple diode + medium u triode
400 pcs PC 900 $ 3,00 high gm VHF triode + audio
90 pcs PCC 85 $ 0.40 double triode VHF
280 pcs PCF 200 $ 0,50 triode + high gm pentode
350 pcs PCF 201 $ 0,50 Triode + high gm pentode
630 pcs PCF 801 $ 0,50 Triode + high gm pentode
370 pcs PCF 802 $ 0,60 Triodepentode
730 pcs PCH 200 $ 0,50 Triodeheptode

150 pcs PCL 81 $ 0,60 Triode outputpentode
190 pcs PCL 82 $ 0,50 Triode outputpentode Wa 7W
200 pcs PCL 86 $ 0,60 Triode outputpentode Wa 9W
250 pcs PFL 200 $ 0,50 Pentode + high gm outputpentode
(S= 22mA/V Wa 5W)
100 pcs PL 36 $ 0,50 Line outputpentode Wa 12W
170 pcs PL 82 $ 0,50 Output pentode Wa 9W
170 pcs PL 83 $ 0,50 Output pentode Wa 9W
360 pcs PL 84 $ 0,50 Output pentode close to EL 84 l
200 pcs PY 81 $ 0,40 Booster diode 550V 150mA
100 pcs PY 83 $ 0,40 Booster diode 175mA

Even more discount is available if you buy large quantities.

Please contact me by fax (+47 57 69 12 67) or e-mail
(arnoldg@enitel.no) if you are interested

anything i find out or know i gladly pass on to those who need the info depending on circumstances,they spy on us so i spy on them,when i first got intp scanners and was still a student i use to pass on information gained at demonstrations that would be of benefit to the demonstrators,in fact it was funny a couple of years ago,when stopped for scanning at notting hill carnival,the cid guy said"you are the one who use to scan at demonstrations",i was well known for that by special branch,and on special or royal events my details use to be passed over by "GT" special ops room at Scotland Yard,they dont bother anymore,they know what i am about and i have a lot of contacts and friends in various police forces,but i dont ever ask them to divulge confidential info,its just that some do.

dont get me wrong,i would not divulge everything,just depended on circumstances.

you could rightly say dangerous,i just stick to my principles and dont get fooled like most people the crap thats fed to us by the current capitalist state.

but you have the right to dissagree by all means.

my politics are just important to me as my scanning

as for CND they thought that it might be useful to have people on the inside,not just me,i still supported what we were doing in the ROC,but although the info gained was not public domain it was hardly top secret.

it amazed me i passed the security checks as i had already been arrested several times at left wing demonstrations,mainly anti nucleur or anti rascist,and i have always been proud of my arrests,i know demonstrate in differant ways.

remember you all can have your say in Brighton on Sunday,the Labour party conference,a very large vociferous but peaceful demo is going to take place[10,000 or hopefully more].

regards

Tantalums have pretty terrible dielectric absorption, and distortion
(for the same value in the same circuit) is worse than the X7R
ceramics I've tested. They are much more expensive than ceramics,
around the 0.1uF range. They are polarized, so you gotta make sure
they are loaded correctly. Leakage seems to be somewhat higher than
ceramics...but polyprop films are pretty nice if you want low leakage!
(I have an ongoing experiment to test the leakage of those, and last
I checked, the discharge time constant was many tens of
years...sub-femtoamp leakage current.) ESR for standard tants is a
bit higher than for ceramics...sometimes a good thing, and relied on
for bypassing some linear regulators. Tants are superior to aluminum
electrolytics in most situations, 'cept for cost. They don't become
open circuits like the alums do at low temp.

Cheers,
Tom

Source record: 49919

A slight addition to the information already given, which is correct. R stands for "RF" and is usually the input; X stands for "IF" and is usually the mixed output. But R and X can be interchanged. Often the X port extends down to dc, or at least a lower frequency than the R port. If your application needs a very low mixed output, then X is the port to use; conversely if your input is lower than the mixed output, then you'd interchange R and X and use X as the input port and R as the mixed output. If your mixer is a Mini-Circuits mixer, you can look up its specs online at Mini-Circuit's webpage.

Tantalum electrolytics are lower leakage than aluminum electrolytics,
but worse than film or ceramic.

If you turn the signal on and it remains on forever, it generates
broadband _noise_.

>The ONLY time sidebands are generated is during the rise and fall.
>Neither the on duration or the off duration generates any sidebands.

If you look at a single pulse, with some nonzero duration, it
generates a discrete line spectrum, with a frequency distance between
sidebands proportional to the inverse of the pulse width. The
available noise power has now been concentrated into these discrete
sidebands. The amplitude of these sidebands follow the sin(x)/x
relationship.

>When we send CW, we increase how often the sidebands generated by the
>waveshape appear. This changes the time-averaged power in the
>sidebands, but it does not change the bandwidth.
>
>The effect is the averaged power in the sidebands increases with
>increasing speed (just as a pulse transmitters average power increases
>with increased pulse repetition rate) but the bandwidth is the same
>for one pulse or a thousand.

Do I understand correctly that you are saying that the total power of
the sidebands will increase with increased number of transitions ?

If so, where does this power come from ? It is coming from the
transmitter. So going from 5 WPM to 50 WPM would turn a 100 W
transmitter into a 1 kW transmitter ?

Unfortunately this is not true :-).

The ratio between the carrier and the total power in the sidebands
remains the same regardless of speed.

>Duration of a pulse does not affect the
>high order sidebands cause by the rise and fall of the pulse, because
>it is at such a low frequency.

The duration of the pulse has a very important effect to the
distribution of the noise power. At 5 WPM, the noise power is
concentrated into small discrete sidebands every 2 Hz. Increasing the

speed to 50 WPM will concentrate the power into discrete sidebands 20 Hz apart. Since one sideband contains the noise power of 10 small sidebands, it is 10 times taller (+10 dB).

Since the power of the carrier level is the reference level and you measure the relationship between the peaks of the discrete sidebands compared to the carrier level (i.e. the attenuation relative to the carrier) and the definition for bandwidth is the (double) frequency offset between the carrier and the sideband at which the peak of the sideband is below a preset level.

Thus, with a few large sidebands far apart, the bandwidth is proportional to the keying rate when the rise and fall times are 0.

Compare this with the situation in a DDS, in which various truncation errors will produce a constant noise power. At certain frequency settings, this noise is evenly distributed on all frequencies and there is a constant white noise floor at say -100 dBc. However, on certain frequency settings, all the noise power is concentrated to one or only a few discrete frequencies, creating nasty birdies only 40 - 60 dB below the carrier.

Message-ID: <3baf6a68.379437158@news.akorn.net>
Source record: 49925

I think I see what is going on.

First most of us probably realize that the only time sidebands are generated are when the waveform changes amplitude. I'm sure most of us understand the bandwidth required for the rise and fall time is much wider than bandwidth required for the actual information in most practical cases, otherwise the CW would sound too "soft".

So we know from that that the spectrum of the sidebands (clicks) is set by the rise and fall characteristics, and not by how often we repeat them.

The probelm is in how we are defining bandwidth.

What most seem to be assuming is we can define CW interference bandwidth using total power accumulated over many dot and dash rise and fall periods. Hence as we double the speed of a given string of characters, we have 3dB more power in a long time window at a given rise-and-fall shape and duration and carrier power level.

That doesn't work well, if at all. For an example of how oddly the brain perceives quick signals, listen to the 1kHz sinewave (as I recall it is 1kHz) tone on WWV that appears once a second. See if that quick pure tone doesn't sound like a click or tick to you.

Once the peak power of any sideband generated by the leading and falling edge of the CW signal is over the threshold of noise, our brains registers a loud click. Neither our brains nor our receivers "store" the energy from multiple repeating busts of energy that are separated by wide margins compared to the duration of these short duratiuon "energy packets".

Now if we were heating resistors, or integrating the energy in a R/C charging system that slowly ramped up with increasing numbers of rising and falling transitions per second, the assumption that bandwidth increases with more frequent transitions would be valid. The level of interference or clicks would sound like it increases in direct proportion to the number of transistions from off-to-on and on-to-off.

Unfortunately that isn't what registers in our minds when we try to operate near another station. What we "hear" are more frequent clicks that extend almost exactly the same distance up and down from the offending station, not more powerful clicks, as that staion sends faster.

Since properly working AGC systems are fast attack and slow decay, they are pretty much charged by one or two "clicks". As a matter of fact, that is how I test AGC systems. I look at the response to a pulse transmitter with short duration and a somewhat large gap between pulses.

If I don't have an AGC system that ramps up faster than the rise time of the CW signal, then the AGC system will thump and distort the desired signals.when on fast AGC. So the AGC, to sound good at high speeds, has to be significantly faster responding than the duration of the rise time. In other words, it has to have a much shorter attack time than the length of the rise time of the signal.

So the AGC system, with the receiver set a given distance from the carrier frequency, pretty well charges to full voltage on the leading edge transition. Increasing the number of transitions per second has little effect on peak AGC voltage, and if we put the meter on slow decay we will see no change in S meter reading as we change the number of "energy packets" sent per second.

Our brains will also not register the difference in bandwidth. For all practical purposes, the bandwidth is set by the rise and fall characteristics and not the number of them per second (or hour or day).

I see now what the problem is. We are trying to somehow define bandwidth as the power over a long period of time compared to what a properly working AGC system or a brain will need to register maximum effect. We are trying to make this time period so long, that the number of transitions in a matter of a second or two becomes unimportant. By doing that, even though each letter has a different number of transitions and a dash has a much slower pulse rate per second than a dot, we are making it all the same and tieing it back to speed.

The problem is, neither our ears or a properly responding AGC system works that way.

That's why when we tune near a novice sending at 5 WPM and notice his rg clicks for 4kHz, it will sound like the same rig clicks for about the same spacing when sending at 50 WPM.

73 Tom

itsw funny how the countries that cause these problems,cannot understand how there arrogance is responsible.

just reading Israels prime minister has refused to talk withy our foreign secretary,just because he righty critsicised Israel.

very similar to the US,must not ctriscise them,they own us,tell us what to do,and now even UK tv reference George Bush as the president,not US president,just president,i was not aware we had one in the UK.

also look at Northern Ireland a problem created by Ulster Unionists and the British,there would of been no IRA,if there had not of been apartheid and racsism towards catholics,which as shown the other week against those schoolgirls is still rife,and there orange marches of course.

these countries and people will not have peace until they realise what they have done to cause the hatred in the first place.

Why would you want a higher ESR for bypassing linear regulators?
Also, aren't the capacitance values used for bypass caps a little
too high for ceramics?

Thanks and 73,
Jim

But the FCC regulations and laws of physics do. No one ever qualified this discussion as being limited to "psycho-acoustic" bandwidth.

THERE'S the missing bit of information. My first exposure to tantalums was in the 70's, when my sources of information were mostly incomplete and I wasn't particularly good at using them anyway. The circuit was a Sylvania TV pushbutton volume control that stored its setting in a tantalum.

Thanks also to Tom for additional details that further complete the picture.

Just read a 1991 book on Soldering. Yes, there is a whole book on it.

Fellow says that one should never resolder a connection. Reasoning:
each time heat is applied the bonding layer gets thicker, and will
eventually fail. Of course, you have to resolder it if has failed.

Wonder if he is right!

NEW PROGRAM *** BOTLOAD.exe

This little program answers the frequently asked questions "What is
the inductance of a bottom loading coil needed to resonate a
vertical antenna and how many turns of what gauge wire ?

Also how many picofarads will resonate the antenna when its input
reactance is inductive ?

And what heights of antenna will give a feedpoint input resistance
of 50 ohms or 75 ohms ? And what loading coil or tuning
capacitance should be used at those heights.

Covers any antenna height from a few inches to several wavelengths
on 160m.

Dimensions in metres, feet, inches and American Wire Gauge.

Source record: 49941

Hi Jim (and lurkers),

Some (actually, quite a few, especially the "low dropout" variety) linear regulators depend on some series resistance in the bypass cap for stability. If the data sheet is good, it will specifically tell you to avoid extremely low ESR. Conversely, some brag about being stable with very low ESR caps. For example, see the data sheet for the Analog Devices ADP3303A, available on their web site. Then look at the applications info for the National LP2981. One says "any cap" and the other says "avoid ceramics."

Some regulators are happy enough (stable) with low capacitance, and others require enough (for stability) that as you say you wouldn't want to pay for the ceramic variety. As for what's needed in the circuit...some regulators are fast enough (and the load circuit constant enough current) that any huge bypassing on the output is just a waste. For one-off circuits, I'd be strongly inclined to toss in a reasonably large tantalum or even aluminum "energy storage" cap, but in designs I put into production, I can spend some time thinking about what I actually need to get the desired performance. Additional bypass caps ('specially electrolytics) add cost and reduce reliability, in that they DO sometimes short-circuit (sometimes burning holes in the board under them). Rule of thumb for best reliability: run caps at not over half their rated voltage, especially if they see high ripple current and/or are in an area that gets hot.

Hope that helps 'splain it!

Cheers,
Tom

I don't recall the US prohibiting or controlling free elections in your
country. Take it up with your own politicians instead of dodging your
responsibility as a citizen by simply crying on usenet. Oh, btw, in the
US, the Queen is normally referred to as The Queen. In fact, I've never
heard her described as The Queen of England or anything like that. If I
use your logic, then maybe we should blame her for the terrorist
attacks?

You seem to have missed an important point. The original
poster said his goal was to increase *receiving* capacities.

What does that have to do with keeping our ever diminishing
ham bands clean?

Absolutely nothing.

Point taken. However I was referring to the original posters over all
attitude. It doesn't matter if it is illegal, just so long as I can do
what I want and anyone who doesn't think that way are "FCC bootlickers"
and like living in a police state. He may not be the same guy who is
operating a 1000W CB radio somewhere in my town and clobbering reception
of the adjacent ham band not to mention the TVI but its the same crap.
I don't know about you but I don't care to be referred to as "boot
licker" just because I prefer to operate radio equipment legally.

ISTR someone having plans for a device similar to the low-power FM broadcast transmitters, that plugged in directly to the motorola-type antenna socket. Anybody heard of this, or am I thinking of something that's commercially available? I would think it would pick up less interference, and would be somewhat more efficient than transmitting out to the antenna.

Failing that, anybody got any ideas for an automatic speaker switch that would allow me to listen to the CD player, but automatically switch both front speakers to the ham rig's output when something opens the squelch? Obviously, it would need to provide loads to the CD player's outputs while it's switched over.

Eventually, I'd like to get everything set up so that I can mix all the audio outputs (stereo, scanner, ham rigs and SW BCB receiver) over the car's existing speakers, rather than bolting more speakers to every available surface.

we are a danger as well becuase all the recent prime ministers have always backed whatever the US does,including the slave labour of there business in the far east,and now our business look for the same slave labour countries to do business in.

but as said.we are just talking freely,we or rather i show no hate towards your or your family,and all those who have spoken are truly sorry for the recent tragedies,but one has to look at the causes before action can be taken.

sadly though i dont think whatever happens now,the world will ever be the same.

regards

I see now!

HOW it actually works in a receiver's AGC system or the human ear
isn't important. The distance we tune and hear the clicks is
meaningless when we are talking about bandwidth.

In other words, it is meaningless that when up the band 3kHz I still
hear the same clicks and see the same S meter reading when speed is
doubled...as long as if I use the clicks to heat a resistor I get
twice the heat with twice the speed.

Very interesting science.

Thanks Jack, and as you can see all the higher speed does is move the
existing close-spaced sidebands further apart while maintaining the
same power level in a given window of bandwidth. Ultimate bandwidth is
the same, the sidebands just move around in that bandwidth.

Average power will increase, however, with speed because there are
more rises and fall per given time period at higher speeds.

Actually, you don't, you're just being sarcastic.

Someone has already gone to the effort to actually collect hard data, using professional test equipment, and placed that
information on a web site for everyone to see. You are wrong in stating that rise times have a meaningful effect on
bandwidth and keying speed does not. Empirical data proves that keying speed DOES effect the bandwidth of a signal.
We will be anxiously awaiting your obfuscating explanation, offering to redefine terms to match your theories, of how HP
test equipment is wrong, and you are right.

Hi Guys;
I have a few BA's that I cannot hold any longer, too big, too heavy & not enough time.
They are pick-up here on Long Island.
1- Johnson Viking Valiant(I) Untested, Extra Nice condition, Best I've seen anyway. Price is $300.
2- RCA RBB-1(?) Navy Receiver, Insides look NEW, No Supply, Built in 1940, Navy type CRV-46147, covers 500 kcs to 4mcs, Has cabinet, & part of the 4 rubber shock mounts. Front Panel is dusty but will be MINT!
Price is $300
3- E.H. SCOTT RCH Navy Receiver, Built in Supply, Original Cabinet with shouck mounts, Super nice, plays.
Price is $300
4- Hallicrafters SX-28, Plays, really clean, nice one guys $400.
5- Viking II, Factory Built, Working, Really nice, nedds a few screws in the Cab.
Price is $250, well worth it!
6- National NC-303 Receiver, The Cabinet if a BUD & very nice but not original. I think its better, plays, Price is $250.
7- NC-183 Receiver, Kind of scuffed up but complete & plays $150.
8- Hallicrafters SX-101A with the 160 mtr band, plays, needs tlc, $150.
All above may need some adjusting, etc. They been unused for years and Will NOT SHIP, Pick-up only.

Wow, you are megalomaniacal. Even hard evidence directly in opposition to your statements is taken as supportive!

You claim, in full context, with your own emphasis, made in a message of 21-Sept-01, was "It is simply the shape of the rise and fall
times that control bandwidth, NOT the off-and-on rate."

It is clear from the final composite, http://home.cox.rr.com/k8zoa/Overlay_shaped_fast__slow.gif, which compares identically shaped keying at both 5 and 25 wpm, that a higher "off-and-on rate" directly results in a higher bandwidth of the signal at ANY given
"db down." So the ARRL Handbook was right, and you were wrong, after all.

Mark, Tom, et. al---

Okay, okay. Let's settle this. I'm tired of hearing all the bickering.

Tom: You're right. Mark: You're right. Good enough?

No? Okay. Here's what I see.

When we alter the keying shape, we attenuate the higher-order harmonics. This is evident on the spectral plot. By attenuating these harmonics, we effectively reduce the bandwidth by altering the skirt of the ``filter''. Instead of having a low-Q filter, we now have a high-Q filter, _EFFECTIVELY_. Trace along the tops of the peaks, you'll see what I mean. _THIS_FILTER_SHAPE_IS_UNCHANGED_BY_KEYING_SPEED_.

When we alter the keying SPEED, we bring the low-order harmonics closer into the carrier, thus making the filter _NARROWER_. The sidebands are still there, and the rolloff shape (Q) is somewhat modified because of it. This effectively brings the -3dB and -6dB points closer into the carrier, _THUS_REDUCING_THE_EFFECTIVE_BANDWIDTH_, as these are the points used to define it.

So, I see where Tom's argument is valid, AND I see where Mark's argument is valid. Both are equally valid depending upon your standpoint.

Can we all shake hands and be friends now?

KK6IL (who cannot post to the NG at the moment) wishes to add the following
to the thread:

The foam in the Kokusai filters does indeed decompose into
a sticky, gooey mess that greatly increases the filter
attenuation.

I've corrected a couple of them, one just last month, a beautiful
unused unit which didn't work.

Bend the tabs on the bottom of the filter to open it up,

Remove filter from case carefully so as to not pull and break
the wires between the transducers and the base terminals.

Scrape off the large chunks of foam without scratching
the metal - toothpicks work well.

Clean the filter disks with Qtips soaked in alcohol.

Clean out the inside of the case.

I repacked the filter in cotton from a standard cotton ball.
Place a little between the filter assembly and the plastic base,
place more inside the case, and reassemble.

Feel free to post this back to the newsgroup to continue the
thread. If I ever get a web page up, I'll post the pictures
I took of the process.

These devices are rf amplifiers from mini circuits, usable from DC to 1GHz. These seem like good amplifiers and they have a 50 ohm input and output, which would simplify the design significantly as there would be no need for matching circuitry. This is one reason I would like to design something with this. However, I have not built a MAR-x amplifier.

Has anyone made a prototype board for this device. Can you use regular pc board material (FR4) for this device? I saw a prototype board in the AARL handbook and it says the only critical dimension is the 0.1 inch strip which is used as a 50 Ohm transmission line. Has anyone made this device and found them useful? Are there better devices out there than are inexpensive? I would assume that with the 50 ohm output, it would be alot easier than transistor amplifier design.

Also, can this amplifier be used as a high frequency 1GHz oscillator with the right feedback components?

5869. Swan Siltronix alignment information free

re: Swan Siltronix Tranceiver, Alignment information.

Hi there,

If you have a Swan or Siltronix 1011 amateur radio... We have great news for you. Not only will you find a web page for the 1011 tranceivers, but we have now writen a brief carrier oscillator alignment text which will appear as a down load icon on the Siltronix (Swan) web page. I also plan to break the page into smaller chapters/sections for an easier down load/web reading.

After the classic golden screw driver has hit your carrier oscillator adjustments, Swan and Siltronix radios are pretty much un-usable. You can now get the radio back into operation by reading the available (free) owners manual and/or suppliment oscillator text writen up. The icon will appear in a very short time, today with a little luck and free time.

Watch for it and feel free to Email questions from the web page if you like.

cheers
skipp

Well, you can buy the little FM modulators quite cheap, and it should be straightforward to modify one to feed directly into a "Motorola" connector. I got a couple of them recently from MCM Electronics at around $10 each as I recall. It is a bit of a problem in a metropolitan area finding a clear channel to operate them on if the antenna is still connected to the radio.

I've also modified an in-dash radio/cassette player by adding a 1/8" stereo jack which opens the audio from the unit and inserts external audio. I can imagine doing that with relay-controlled insertion...in some ways it might be easier. It was some fun finding a place on the front panel of the unit to put the 1/8" jack...I had maybe half a dozen jacks in different form factors, and only one of them would fit. (Not the smallest, actually...just the one with the right shape.) Running four small shielded leads out to an external relay would have been easier but left things messier. The radio was 1986 vintage, with mechanical volume controls. Modern ones almost certainly use electronic controls but if you are willing to poke around in the guts, you can _perhaps_ find a place to break into the audio path. If a single IC is used for control and source selection, it's not so easy--unless you get really lucky and find spare inputs you can select.

If your unit plays casettes, you can perhaps use a fake casette that magnetically couples to the tape heads, to feed audio. These are commonly available...try CD shops or consumer electronics stores. They have a 1/8" stereo plug on a cord that you feed line-level audio to.

It's very unlikely that you'd need to load the speaker outputs if you simply switched the speaker leads. Modern solid state audio power amps don't much care about open circuit loads...many (most?) don't even care about shorts. But beware that the outputs may be "bridged" meaning that neither speaker lead is grounded. So be prepared to switch _both_ speaker leads to each speaker.

If your unit happens to have an external power amplifier, you have yet another place to break into the audio path...the cabling that goes from the in-dash part to the amplifier.

Hope these thoughts help...

Cheers,
Tom

NY/NJ/PA (Radio) Octoberfest

Fellow Radio Aficionados!

You are all invited to (Radio) Octoberfest at Verkhovyna Mountainview Resort in Glen Spey, NY (NY,NJ,PA tri-state area) hosted by the Tesla Radioclub and Ukrainian-American Cultural Foundation - UACF on October 6, 2001, starting at noon till ???

Come and have fun meeting other hams, DXers, contesters, while having good time and drinking Octoberfest beer. Enjoy Ukrainian and German food, listen or dance to endless polka's. Wear your badge, hat or shirt with callsign proud and meet other radio aficionados around the "radio" table.

140 acre Verkhovyna resort is the new home to Tesla Radioclub N2EE station. Join the semi-serious discussion of how many towers do we need to put up there. Come, join the club and get a free beer.

Directions:
Take Hwy. 84 to Port Jervis, NY, NY exit 1; follow Rt. 6 through Port Jervis to traffic light with Rt. 87/42 signs, go through and follow Rt. 97 west for 10.8 miles to Pond Eddy (motel on right, bridge on left), turn right onto High Rd. (Rt. 41), go up the steep hill for 1.7 miles, Verkhovyna is on the left. Plenty of parking.
Maps are at www.UACF.net home page.

See you all there and join us yodeling in Morse code :-)
Nazdorovya, Prosit!

Yuri, K3BU
pres. Tesla Radioclub

I have. You can use FR4 if you don't care about high frequency
rolloff. Glass Teflon-Epoxy is not much more expensive (epsilon=2.2)
and it has slightly better and more consistent loss characteristics.

It is easier to work with in some respects because, as you say, you
don't need to match it. However, don't expect a really good noise
figure or great IMD numbers. They're designed to be wide-band
amplifiers which can simplify a project and reduce parts count.

>Also, can this amplifier be used as a high frequency 1GHz oscillator with the
>right feedback components?

To answer your question, you CAN use them in oscillator circuits, but
they weren't designed for such service, and frankly you'd find your
self working at least as hard to make an MAR series of device work as
you would any discrete active device.

Given how easy it is to work with computer software for amplifier
design these days, as an amateur, I would really question whether it's
worth using them.

Let's say, just for a minute, that it wasn't some nasty Islamic radical that caused the atrocities of two weeks ago, but, rather it was some warped "Michigan Militia" men.

Would the appropriate tactic then be to bomb Detroit?

Joe:

I use an FM modulator designed for a JVC CD changer. The local electronics store was having a sale on miscellaneous "open box" products and I got the unit (without the changer) for $11.00. It contains an antenna relay to switch the modulator in and the antenna out when it is activated. I use the switched power pin on the back of my IC-706MKII to power it, so when the transceiver comes on, the modulator automatically connects to the car stereo. I've found this to be very effective. Having 8 speakers, 200 watts of audio, and tone controls makes the system much more flexible than using an add-on speaker.

I had previously tried some low cost ($10-20) modulators made for attaching portable CD players to a car stereo, but found them to tend to drift and have poor audio quality. The modulators designed for CD changers are typically crystal controlled and have excellent audio quality. If you find a place that sells them new, they run in the $50-100 range, but if you search a bit, you should be able to find one that has been "orphaned" like I did for not too much.

as for the USSR the cold war was the biggest hoax in history,when exactly were we in danger,even during the cuban missile crisis,at the end of the day we and the US were more than happy to point all there weopons in Germany at the USSR ,but the americans did not like the fact that they had the same types of weapons pointed at them,rather smilar to what unfortunately happened two weeks ago,fine if we do it against other countries but,somebody attacking us.

as for minority,i think it is the view of the majority of the british replies on the subject,yes go ahead ignore,as you normally do but its at your and our peril as we are likely to get terrorist attacks now as well.

yes go in and get Bin Laden and his cronies but unless yours and our foreign policy this is never going to end.

criticism does not mean we dont grieve with you,its not personal[or should not be],but how does the west expect to be popular with the east and middle east when we support slavery in those countries and do nothing to protect them,do you remember Tianemen square,we were too scared to help but picking someone with no nuclear weapons is an easy target.

regards

Whatever else the cold war was, it was not a hoax. Many people died on both sides, and
each side was deadly serious about destroying the other. The only thing that kept what little
peace there was, was the threat of mutually assured destruction. Moreover, weapons of
mass destruction were programmed to destroy Europe as well as the U.S. and Russia. Everyone, worldwide,
was in danger. You would do well not to let your dislike of current American military and
financial hegemony distort your view of history. It does you little credit, and promotes false and
dangerous attitudes among those gullible enough to believe you.

there we go again quoting that free world tripe.

those with lots of money are free,most of us are slaves to our jobs,barely making enough to keep our families,that just in the west,for those in the former USSR and other countries spoilt by capitilism,capitilism can work but it can and should be a lot fairer,remember the the only low paid workers in the WTC,were the cleaners/security/chefs etc why should they get less than those pen pushers sitting in offices on there bsacksides earning lots of money for nothing.

if one good thing comes out of recent events,i hope that the real workers of the world get together and overthrow the current system.

Tony Blair and co are reputed to be getting bloody noses in Brighton this weekend,it will be fun.

he can have his war,others can have theres,it all fair in love and war as they say.

5885. Measurements

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-27 00:00:32 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9otqf2$co0$1@plutonium.btinternet.com>
Source record: 49881

10 percent of the reliabilty and accuracy of measurements is due to the quality of the measuring instruments. However, regardless of the reputation of the instrument manufacturer , the other 90 percent is due to the person making the measurements and his technical judgement.

Measurement results obtained by anyone claiming his measurements are good simply because he uses a particular manufacturer's instruments should be automatically discarded as unreliable. The manner of his claims themselves betray ignorance of measurement principles. He lacks confidence in his own ability. He resorts to name-dropping.

The most reliable measurements are made with the most simple and inexpensive instruments by someone who understands the subject matter.

KISS

Go for it.

These devices are easy to apply, and they work as advertised.
I stock MAR-2, MAR-6 and MAV-11 in my junkbox.

It's not that critical (and some basic research would have
lead to the same conclusion). Use 2.5 mm tape, or lay it out
by hand. It works fine. FR4 or other relatively lossy board
can be A Good Move. A bit of loss helps keep things stable.

Don't take *my* word for it: try it and see. Hams did this
at one time, you know.

> Has anyone made this device and found them
useful?

They are extremely useful.

> Are there better devices out there than are inexpensive?

Define "better". Cost? Gain? Parts count? Noise? Isolation?

> I would

> assume that with the 50 ohm output, it would be alot easier than transistor

> amplifier design.

Yes and no. Look at the power consumption and decide if the low parts
count is worth it.

> Also, can this amplifier be used as a high frequency 1GHz oscillator with the

> right feedback components?

Any amplifier will oscillate. The loop gain is kinda
high, and there are better ways of solving the problem.

I like the MAR series amplifiers as general purpose gain blocks. They
also make convenient LO amplifiers for driving double balanced mixers.
Pick an amplifer that compresses at the right output power and you can make
the drive to the mixer consistant across large tuning ranges.

For high dynamic range amplifiers, I use discrete devices, but for a lot
of applications a MAR is hard to beat for cost and ease of use.

An avid Weekend Barganhunter...(garagesales) I've come across wuite a few electronic components real cheap.. Mostly old computers and parts for them... Recently i have started removing components from some of the circuit cards... In particular i am intrested in removing a 556 timer and several 74 family chips I was wondering if somone could provied some methods on desoldering... and removing components withought damage...

5892. Re: DeSoldering-Removing Parts...

I've removed through-hole leaded ICs from boards by turning the board upside down, heating the non-component side with a propane torch, and rapping the board on the bench. Don't let the torch stay on one area too long. I wouldn't try this with surface mount parts, and it does destroy the board itself. But the ICs I've recovered have all survived. Practice on some throwaway components first, and I wouldn't do it indoors because of the fire hazard.

you discuss it on whatever group you want,we are adults with a common hobby
and true we should speak about that on this group,but whats the problem??

you do not have to read,i enjoy on all groups including my own
yahoogroup,good conversation,if we go off topic sometimes,and as said this
is a major one,one should not need to go on another more relevant
group,particulary if the discussion started on here.

rules are there for the breaking,thats what scanning is all about anyway.

Radio Shack has a desoldering iron that has a vacum bulb on it to remove solder as you heat it. There are several kits available that have tools by which you can remove the whole chip at once by heating all of the pins and pulling it out. Chek the Rat Shack catalog for those as well. The torch idea is a good one too but as Roy says it should be done outside AND you do need to practice on a junk board a couple of times.

The quickest and easiest way is to heat the underside of the board with a
blowtorch around the chips you want to remove, and wack it down on something
hard. The chips should fall out. It's probably a good idea to do this
outside. 8-)

You can use ordinary FR4 for a simple amplifier. It won't work very well for
more complex microwave design using microstrip, because it isn't
characterised properly for the frequencies involved.

Electronics World had an article a few years ago about using this type of
device as an oscillator. It worked, but wasn't all that good. I can't
remember what the problems were.

I've used a hot air gun as a way to heat the board for melting solder...
It'd be safer then a torch, but works well enough.

Something like a hair dryer, but this one was bought at a hardware store
and I think is rated at 1200 and 1600 watts.

Best way is to purchase a de- soldering station with controlled heat,suction,etc..that is quite expensive, so, get a small iron with temp control ,get a roll of copper wicking,and a solder sucker. you can get that at a local supply , Radio Shack...practice and be careful, you will get the nack of it and be able to save most of the components. good luck W4PQW

That is the whole point, Proma. These groups are about Amateur Radio
and this discussion isn't. Secondly, this hasn't been a good discussion, it
has been more of a way to lob insults at each other. This discussion isn't
helping anything, it isn't informing anyone, so what is the point.
My point, was that we should drop the thread, because it is serving no
purpose at this point and that it is causing some people to take a childish
attitude and it isn't doing any good for the group. Not only that, but it
is detracting from the "spirit" of Amateur Radio.
My point was put well by Jon Harris, "...it doesn't mean that this is
the right place to discuss it..."
Have you looked at what groups your cross-posting to? They are
alt.ham-radio.vhf-uhf, alt.radio.scanner.uk, rec.radio.amateur.homebrew,
uk.radio.amateur, uk.rec.radio.cb

This takes two people... Put the board in a vise to hold it firm. Then the first worker uses slip-joint pliers to grab the ends of the chip-to-be-removed, grip it firmly, and pull rather strongly. The second worker then, on the solder side of the board, hits all the chip's pins with the flame of a large propane torch. As soon as the second sees the chip pull free, he takes the flame away.

This is hard on the board, but not on the chips. The secret is to have a flame big enough, and to work FAST. We used to do this back in the 1970s to take large numbers of memory chips out of surplus boards from obsolete mainframes. It really does work.

5907. Re: OT : CW Bandwidth

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-27 21:26:04 UTC
From: 2w8ji@contesting.com
Message-ID: <3bb3920c.42726014@news.akorn.net>
Source record: 49803

OK, so we have all the explainations of how bandwidth changes. Good enough. Anyone can make a mistake, and I was almost convinced I had a bad memory. I was working from my recollection of what I measured and observed when measing keyclicks on various radios.

Sooo, I did a quick setup today and ran a test with my FT1000D because it has a filter I can switch in and out. I can make it stock keying, or my modification that makes filtered CW keying. This mod was the result of complaints that I was "clicking up the band" by other DX'ers when working a close split.

I have a homebrew receiver with a double balanced high level mixer, followed by a push-pull CATV transistor amp into a 600Hz 6-pole filter followed by another high level mixer into a 250 Hz filter. This receiver has a two-tone IM DR of over 110dB @ 2kHz spacing, and a blocking DR about 120dB or more (my generator noise limits the blocking test at 2kHz spacing).

The FT1000D has composite noise (mostly from transmitter IF amplifiers) that extends over the whole band, but it is about 100dB down.

I transmitted on 1823.5 kHz with a string of dots (using a keyer that displays WPM). I closed my eyes and tuned the receiver up towards the carrier while sending dots, and stopped when I could clearly hear clicks. This is what I measured:

Yaesu stock poor filtered CW:
5 WPM 1822.1
40 WPM 1822

Click modified filtered CW:
5WPM 1823
40 WPM 1823

Repeating the test poor filtered

5WPM 1822
40 WPM 1822

Repeating the test filtered

5WPM 1823
40 WPM 1823

Now that we know the "transmitter bandwidth" changes with clicks, why doesn't it change a measureable amount?

By the way, this is almost identical to what I recall looking at several other rigs. I recall always hearing the click the same distance away regardless of speed.

Something is very odd when bandwidth increases but the bandwidth does not increase.

My problem is in understand what something in the future or past means to a given instant of time. The click only occurs during the rise and fall window. While it might matter to a FFT analysis what a string of dots does, it sure doesn't matter to a receiver that is not being overloaded or blocked!

Why?

another method..alot slower than the torch..is to buy a desoldering
iron from radio shack..the type with the suction bulb built into the
soldering iron fixture..it has a special tip with a hole to allow the
solder to be sucked up away from the joint (with the rubber bulb)..it
works quite well..you can buy replacement tips..when the units and
tips were on sale..i bought some up as spares...73 Earl VE3AB

I can! I was asked to try that circuit in a wideband oscillator. It
really worked poorly because the system used L/C phase shift to make
the feedback the correct phase.

The problem is the phase changes so gradual over a wide frequency
range, the thing was jumping and wandering all over the place in
frequency.

Also, MMIC's don't limit well and you can't modify the saturation or
limiting like you can with discrete componets. They make very very
poor variable oscillators in my experience.

They are OK for amplifiers but seem to have high harmonic distortion.
I use devices like the MAV-11 in sorta-low-noise amplifiers in
filtered applications and they are fine, like as a post-mixer amplifer
driving a crystal filter. You can certainly do better with descrete
components.

I've had no success using them in push-pull broadband applications.
Has anyone else?

low paid unskilled usually work harder than those in banking and office jobs,so in a fair society they should get a better share of the worlds wealth.

as for Brighton,large demo planned,and also intelligence reports to the police passed on to me by press contacts is that the conference is likely to be a terrorist main target on Sunday.

i like the norman tebbit adress,may be i could use osamabinladen@baldock.com

this is good fun,but we cant keep it up forever,in brief all i say is just look at the world,reaearch your facts and history.
[mind you even that is flawed,books as with any media is going to be biassed according to our own biasses]

at least we can share our views,so although i have serious views on the current world,and those who lead it,i know they are my views,right or wrong depending on your viewpoint.

terrorism is the poor mans war,he cant buy jet fighters so he uses passenger planes

ok ossama is not poor,but still he has no access to jet fighters.

many people we considered terrorists are now well respected,as we gain more info on someone we realise that it was the only way out for some people,in a world that does not listen.

The Icom 706 is the best 6 meter rig available.

It has Subaudible tone encode and decode built in

Also, I found out that the hustler mobile antenna resonates exactly in the
middle of the 6 meter band with no coil installed.

Have fun.

Forget all that microstrip junk. Just solder the thing down to a piece
of bare copper-clad board and keep your connections short. You'll lose
a dB at most.

The presence (and proper choice) of a power-supply choke is MUCH more
important to these devices than fiddling around with exotic substrates
and precision cuts trying to get a 1.000001:1 SWR.

What is the application here? A notch filter will only take out a
single frequency. What you're describing would be more of a band reject
filter, typically comprised of a combination of low-pass and high-pass
filtering. But, if you're wanting to only notch out a single signal
somewhere inside the range stated, a notch filter would work.
Is this a transmitting application?
A single freq notch can be easily made with a coax stub trimmed to the
freq of interest.

Source record: 49816

Not familiar with MFJ box, I use an AEA CIA. Technique should be the same, however.

Disconnect the plate end of the choke from tube and tank circuit, attach it to analyzer center conductor terminal. Ground analyzer shield terminal to chassis. Other end of choke will be effectively grounded through the bypass caps on the DC side.
Don't move the connecting wires too much, you want to include parasitic capacitance in your measurements.

Sweep the analyzer across the frequency range. Watch for impedance dips indicating series resonance. Note frequenc(ies) at dip. Watch for x = 0 at any frequency. This will indicate resonance. Impedance peaks indicate parallel resonance, not always good due circulating currents in the choke. Ideally, resonant points should fall outside ham bands.

If your analyzer doesn't read reactance, you can insert a 50 ohm resistor in series with the choke and sweep looking for minimum VSWR points.

150 what plus shipping? US dollars?

Have a look at http://www.rswww.com. For £103 (approx US $150) they will
offer you a new power supply with outputs:

+3.3V @ 23A
+5V @ 32A
+12V @ 12A
-12V @ 1A
-5V @ 0.5A
+5VSB @ 0.1A

RS are hardly the cheapest supplier around either...

The insults have mainly been lobbed from one side, always when faced with arguments which they can't or don't want to deal with. I for one learnt a lot from this discussion and found it interesting.

I still can't understand why people can't just ignore threads that don't interest them. I am reading this on rec.radio.amateur.homebrew. Each day I automatically ignore a large number of posts by people selling commercial radio equipment, because it doesn't interest me (nor do I see how it relates to homebrew). It's not that difficult...

>40 WPM 1822

I don't know psycho-acoustics well enough, but some of these things
may contribute to your observations.

At 5 WPM, the fundamental is at 2 Hz and odd harmonics every 4 Hz,
thus, there are about 60 discrete harmonics in the 250 Hz band.
At 40 Wpm, the fundamental is at 33 Hz and odd harmonics at 66 Hz
interval with 3 or 4 harmonics in the passband.

I am not sure how the ear/brain system responds with some form of
addition to 60 weak or 3-4 strong harmonics in the passband. You might
even get different results with the BFO above or below the receiver
passband.

There is also the special case when the BFO is at the Tx frequency and
thus, the recovered audio tones are harmonically related to a
filtered-out fundamental tone.

It is interesting to note that you can "hear" a very low tone (10-30)
from an organ even when listening through small speakers with 100 Hz
cut-off due to harmonic reconstruction in ear/brain.

I would not be too surprised, if putting the BFO exactly on the Tx
frequency might produced some strange sensations.

>dots does, it sure doesn't matter to a receiver that is not being
>overloaded or blocked!
>
>Why?

Because CW is usually injected as an audio tone into the usual SSB TX.
It will be filtered in the TX chain before the receiver has a chance to
see the 'real' sidebands.

With this tone set to the middle of the TX SSB filter you might expect a
bandwidth of +/- 1.5kHz which is roughly what you measured before
modifying the rise and fall times.

There, everyone's right ;-)

According to the ARRL Handbook, Appendix 6 of the CCIR Radio Regulations and Section 2.202 of the FCC rules, a 5 wpm code stream will use
about 12 Hz of bandwidth. According to the sources already quoted, and Shannon's law, the speed/bandwidth relationship is linear. An identically
shaped 40 wpm code stream would consume approximately 100 Hz of bandwidth.

You are attempting to measure, using subjective senses and uncalibrated equipment, the change in bandwidth occuring on one sideband,
a change of approximately 44 Hz. The measurements you report indicate you are measuring with a resolution of 100 Hz. It's not surprising that you
can't measure a difference, given the method of measurement.

> My problem is in understand what something in the future or past means
> to a given instant of time. The click only occurs during the rise and
> fall window. While it might matter to a FFT analysis what a string of
> dots does, it sure doesn't matter to a receiver that is not being
> overloaded or blocked!

The consumed bandwidth is not a constant, but rather best thought of as a moving average. If you send a 50 dot-per-second stream, it should be
easy to see why you would have a 50 Hz sideband component (you're sending a 50 Hz square wave). If you send a string of dashes at the same
speed (3 x dot), it will create a 17 Hz sideband component (the dashes) and a 50 Hz sideband component (the spaces between the dashes). Letter
spacing adds a 17 Hz component, and word spacing an 8 Hz component. Hold key down, and all of that goes away. Add the harmonics, and the
consumed bandwidth is greater. Shaping controls how higher harmonics drop off, but speed controls the sideband. It should be easy to see that if

you widen that sideband, then the higher harmonics will widen also independent of shaping, because they're simply multiples.

>can't measure a difference, given the method of measurement.

I disagree. My receiver is calibrated quite well, better than most spectrum analyzers. Not only that, it does not need to sweep.

Please tell me what could possibly be wrong with my reciver? It is a good receive, it can read frequency to within 100Hz, and I am measuring something 1.5kHz wide.

Not only that, it is HOW the signal affects receivers that determines the bandwidth required for operation.

The receiver can "sit" on one frequency and give a real-time observartion of clicks. The spectrum analyzer or an FFT system can NOT. The spectrum analyzer or FFT system requires many clicks (or dots) to proivide a result, so phase is important and can color the results. With a receiver, you hear one click and it is gone. Same with the brain.

The bandwidth at which I can hear a click clearly does not change a noticable amount with dot speed for a given rise and fall shape and duration.

>The consumed bandwidth is not a constant, but rather best thought of as a moving average. If you send a 50 dot-per-second stream, it should be

50 dots per second would never be realistic, and would require a thousand Hz bandwidth with normal CW shaping. What possible difference does it make if the primary sidebands are out 2 Hz or 50Hz when the sidebands caused by the rise and fall times are out many kilohertz?

We keep getting into unrealistic speeds and rise and fall times (and bandwidths) while ignoring the harmonic energy necessary to generate the rise and fall in order to justify something that appears to be wrong, even though commonly understood to be correct.

When the rise and fall time is significantly faster than the modulation off-and-on rate, the rate does NOT affect the bandwidth at all. It makes no difference at all if you add sidebands of a 10 Hz signal to a signal that is alread 500Hz wide because of rise and fall characteristics.

After all, you are adding LOWER frequency sidebands by keying, not HIGHER frequency sidebands because the rise and fall sidebands always have to be much wider than the sidebands caused by information.

The ratio of carrier power to sidebands changes, and is reduced with increased speed. The distribution of sidebands within that bandwidth is changed, but the bandwidth and slope of that bandwidth remains the same as long as the elements being sent are significantly longer than the rise and fall times.

No one uses a 50Hz shaping filter on a transmitter, and a 50Hz filter on the receiver.

Here is what I received in private e-mail:

To: W8JI@contesting.com
Subject: Re: Clicks

Tom,

That is all correct, always assuming as you did that the pulses are much longer than the rise and fall times, those times dominate the problem. I am attaching some notes where I plotted the spectrum generated from keying pulses of 20 ms and 50 ms both with 4 ms rise times. You can see how the pulse length effects the spectrum. The details
are changed. The central peak corresponding to the carrier has more power
for the longer pulse as it has too, and that peak is narrower. It is probably this effect that others are thinking about, however
the overall width taken up by the sidebands is independent of the pulse length until it gets to be around the same as the rise and fall times.

end

I'll post the plots on a web page if and when I get permission.

What I would do is go to the local public library. If they don't have
'Radio Communications' they could locate another library that could.
Then they could either get an interlibrary loan, or (if you knew for
certain what articles you wanted) have the other library copy the
articles for you, for a nominal fee.

This, of course, is if you are in the USA. I beleive you are not, and
I am not sure if other countries have the network of libraries like we
do here.

So you are now claiming that a 40 wpm morse code stream consumes 1.5 KHz of bandwidth (or is it 3.0 KHz, since your
methodology only measures the change in one sideband) !!!??? I guess we should get rid of the CW portions of the bands,
since you've just proven (!) that CW consumes the same bandwidth as SSB!?

With that logic, the sidebands go out ad infinitum, you just don't have a receiver capable of detecting them. 50 dpm was
used as an example; divide all the numbers by whatever factor you wish, the concept will still be valid.

You keep focusing on the rise time independent of the keying rate. You have stated "My problem is in understand what
something in the future or past means to a given instant of time," which is a good summary of why you do not understand the
issues involved. Bandwidth exists in the frequency domain, where time is intrinsic.

Something to consider. We all know (or should know) that a square wave is made up of odd-order harmonic sines. The
harmonics are defined by the appropriate Fourier expansion: s(x) = [sin pi x - (1/3)sin 3 pi x - (1/5)sin 5 pi x + (1/7)sin 7 pi x + .
.ï¿½] It should be clear (simply because it's a fact) that the higher the frequency of the fundamental (keying rate), the wider the
bandwidth used.

What harmonics are generated by a single key down event with instantaneous rise time? If the key is released 1 second
later, what happens? 0.5 seconds later? Your argument is that the same harmonics are generated in each case, but reality
(and Fourier) says that the harmonics depend upon the time between these events.

The point is, an event cannot be separated from past and future events when examining the frequency domain, because
without the time component, there is no frequency.

>into the carrier....

Don't wish to be confrontational - but wasn't this Tom's point from the very start ?....

.... that the effects of keying speed on the lower harmonics (which he acknowledged to be relative to keying speed) were less significant than the effects of envelope shape during rise/fall times on the higher harmonics (which would be determined by envelope shape or rig design and independent of keying speed) so the widely-accepted statement "more information requires more bandwidth.... the faster you key the more bandwidth is occupied by your cw signals" is _EFFECTIVELY_ incorrect because it fails to take into account what is happening during the rise and fall periods.

I find this discussion truly fascinating. How can so many people with so much experience discuss this for so long and still not come to a consensus about a technical issue such as the bandwidth occupied by a CW signal and whether it is or is not relative to keying speed? I don't think it's just personality differences. The 'widely-accepted view' seems to be an oversimplification and maybe we should reconsider the way we think of cw bandwidth.

Source record: 49839

The capacitance of all semiconductor diodes changes with reverse bias. The only things that distinguish a varicap from any other diode is that the capacitance characteristics are specified, and that in some cases the doping profile has been altered to produce a particular shape of C vs V curve. For one-off applications, where you don't need to be able to exactly duplicate the circuit on a mass production basis, you can use other diode types in place of varicaps. I've often used Zener diodes in HF applications such as pulling a VFO for RIT because they have a relatively large amount of capacitance. In general, the lower the voltage rating or higher the power rating, the greater the C. Transistor emitter-base or collector-base junctions can be used, with the emitter-base junction giving you a lot more capacitance. Likewise, you can use a JFET junction. A small-signal silicon diode like a 1N914 also varies with reverse bias, but the capacitance is very small, so it's generally useful only at very high frequencies.

<Cue Crocodile Dundee> That's not a torch. THIS is a torch!

Seriously, speed is important or else you'll cook the ICs. You need something the size of a blowtorch or a 2kW hot-air gun, that can heat the back of the board up fast.

The hot-air gun is for lots of other things - such as heat-shrink tubing, or pre-heating PL259s so your soldering iron can handle them. Given how cheap they are, I'd recommend you get one.

ram,

What you are experiencing in reading these exchanges is a demonstration of the fact that most of this "radio" stuff that we deal with daily and take so lightly is in reality extremely difficult material, both in its physics and its mathematics. Sure, you don't need to know much to get a ham ticket - especially these days - but having reached that goal does not usually qualify one in many areas of the technology.

Like an onion, there are layers of complexity and meaning. Most hams - non-professionals, that is - see only the general outline of the onion or maybe have had a peek at the first layer or two. The guys who labored through grad school and put in decades of their lives to gain the experience they enjoy now see many more aspects of the situation than others. And since not all of *them* are always seeing and talking about the same layers, they run into disagreements over terms and concepts which seem to the layman to be nonsense becuase their meanings should be so obvious to everyone.
But, they are not.

We are blessed to have enormous talent on this and other amateur newsgroups and lists. I personally have learned much from reading these discourses despite being one of those guys who has ventured pretty far into the onion over the years, both in school and work.

In general, each viewpoint that you read is probably more *right* than *wrong* and the apparent conflicts are usually based upon concepts and principles that probably elude most of us.

So, bear with it and take the opportunity to polish your own understanding - I do so daily.

To which you divert to:

>So you are now claiming that a 40 wpm morse code stream consumes 1.5 KHz of bandwidth (or is it 3.0 KHz, since your
>methodology only measures the change in one sideband) !!!??? I guess we should get rid of the CW portions of the bands,
>since you've just proven (!) that CW consumes the same bandwidth as SSB!?

It is the rise and fall times and shape that sets bandwidth of clicks,
not the speed.

For any rise time and shape, the rig must generate sidebands that
allow that rise. Click. The same is true for the fall. There is no way
around that.

And yes the FT1000, FT1000D and FT1000MP and many other rigs now are
notoriously and needlessly wide. There is no need to occupy 3kHz to
send 5WPM or even 40 WPM CW. Perhaps the factory engineers have
misinterpreted what affects bandwidth of CW, and don't understand why
a smooth round transitiuon from zero to full power and back down is
needed, without any sharp corners, and they somehow think bandwidth is
tied to speed instead of rise and fall times and shape.

>With that logic, the sidebands go out ad infinitum, you just don't have a receiver capable of detecting them. 50 dpm was
>used as an example; divide all the numbers by whatever factor you wish, the concept will still be valid.

The point you miss is the rise time and fall time generate harmonics.
It doesn't maytter if I only push the key once this year, and never
again, or fifty times a second....those sidebands are there at every
push.

That is the click that bothers people up and down the band.

That click is filtered or limited by whatever shapes the rise and
fall. In the FT1000 series, that is mostly the SSB filter since the
fileter is driven with an almost perfectly square envelope. With a
transmitter SSB filter 3dB BW of 2.4KHz or so filtering the sidebands
(clicks), it isn't any wonder at all I hear clicks down 1.5kHz no

matter what speed I send.

>You keep focusing on the rise time independent of the keying rate. You have stated "My problem is in understand what
>something in the future or past means to a given instant of time," which is a good summary of why you do not understand the
>issues involved. Bandwidth exists in the frequency domain, where time is intrinsic.

That is the problem. In my receiver, or in my ears, the click is all gone before the next one comes along. What happens in the future, or the past, does not matter to either my ears or the receiver because the click has decayed to nothing before the next one appears.

Since we are talking about the interference bandwidth of the CW signal, and since the interference is caused by clicks, it matters not a bit what happens after any click is gone. Neither my receiver nor my ears store the previous click, or anticipate future clicks.

>What harmonics are generated by a single key down event with instantaneous rise time? If the key is released 1 second

>
>The point is, an event cannot be separated from past and future events when examining the frequency domain, because
>without the time component, there is no frequency.

We listen in real-time.

The whole concept of frequency domain is wrong when used in this application. The concept of bandwidth increasing with spped only applies if some spectrum remains in the system when the next sideband comes along. It does NOT remain in this case.

I think what has happened, is someone at some time started applying the wrong analysis to clicks. They forgot the receiver does not respond to dc, and does not "hold-over" one click to the next in some sort of storage. Neither does the brain, untill the clicks become more like a tone.

We are using receivers, not storage scopes, to copy CW. It is the response of a receiver that matters.

So it appears that FT1000x is actually transmitting J2A and not A1A,
i.e. an audio oscillator is keyed and the signal is fed to an ordinary
SSB transmitter and the "CW" mode selection only affects the frequency
display, showing the actual transmitted frequency, not the suppressed
SSB carrier frequency.

If this is the case, then the test results with 5/40 WPM that you
previously posted are completely bogus and prove nothing about the
effects of keying speeds and transition slopes.

Assuming the keyed audio oscillator is running at 1500 Hz, it will
generate a rich set of odd harmonics every 4/33 Hz down to zero (and
images due to "negative" frequencies) and up to tens of kilohertz.
Since the SSB transmitter uses some sort of crystal filter to limit
the actually radiated bandwidth to +/-1200 Hz from the carrier, the
last harmonics that will be the 600th resp. 72th that are about -55 dB
resp. -37 dB down from the carrier. Any harmonics with a higher number
will be filtered out by the sharp crystal filter.

It is quite obvious that the offset at which clicks are detected will
be about 1500 Hz due to the +/-1200 Hz from the Tx filter and +/-125
Hz from the receiver filter, so the test really proves nothing about
keying waveform shaping.

BTW, is the low click modification simply that the Tx signal is routed
through a narrow (500 Hz?) CW filter instead of the stock SSB filter ?
No wonder that the results are the same for both keying speeds, since
the bandwidth is simply set by a crystal filter.

Source record: 49845

Both Tom and the people doing frequency domain analysis are right.

A few days ago I posted a verbal description of the spectrum of a string of dots (a square wave) with and without rise/fall time filtering. Jack, K8ZOA, posted some measurements which show the spectra in graphical form. Yet Tom listens with his receiver tuned away from a transmitter frequency and hears a click each time the dot is made or broken, and its amplitude doesn't change with keying speed regardless of how far away he tunes.

The problem is that Tom isn't listening to the signal with a spectrum analyzer, so he's not hearing what the spectrum analyzer shows.

There are several ways of looking at this, and the one I've found most comfortable is a combination of time and frequency domain analysis. First, consider the spectrum of a single step with instantaneous rise time. The spectrum is continuous, that is, it's not composed of discrete lines. Its shape is 1/f, so if you look at the voltage or power at one frequency, it'll be 6 dB less at twice that frequency, or 20 dB less at ten times that frequency. In the theoretical case, where the step lasts forever, it has infinite energy, and the spectrum keeps getting larger and larger at lower and lower frequencies. In reality, of course, the step ends at some time, limiting the low frequency spectral amplitude. If we run this step through a lowpass filter to limit its rise time, the spectrum drops more rapidly at frequencies above the filter's break point, just as it does with a repetitive square wave.

The important point is that the single step contains energy at all frequencies, and the amount drops as you go higher in frequency. When the step is modulating a carrier, the spectrum is simply shifted so it's centered at the carrier frequency, and a mirror image appears on the other side of the carrier. The fact that it contains energy at all frequencies means that if you put a step into any kind of filter, something will come out of the filter. That is, the filter will ring for a while. Suppose you put the step into a band pass filter. The filter will ring for a while, then die out to zero, where it started before the step was applied. (It would have to be a lowpass filter, with response down to DC, in order to avoid decaying down to its initial state.) What we'd hear is a click if the filter didn't ring too long. Now suppose that after the filter has completely (for practical purposes) returned to its initial state, we apply another step, either upward or downward. The filter will produce another click just as before, and return to its initial state. If we put steps in more and more rapidly, the filter will produce clicks more often, but they'll be the same amplitude as before.

This is what Tom hears when he listens to the receiver tuned away from the signal.

If the step is run through a lowpass filter to limit its risetime, the amplitude of the spectrum above the filter's breakpoint is reduced. Consequently, if you're listening to the signal at a frequency farther away from the carrier than filter's breakpoint, the amplitude of the click will be reduced.

Why don't the clicks get louder when the keying speed increases?

For the clicks to get louder when keying speed increases, some of the energy from the upward step has to still be around when the downward step occurs. It's the summation of these bits of energy that make up the different spectra as the keying speed changes. This requires a filter with different characteristics than you'll probably find on a communications receiver. As long as the effect of one step has died out by the time the next one happens, you'll hear the same thing, at the same loudness, regardless of the keying speed. It's because you're starting from scratch each time.

The spectra that Jack and I described are real, correct, and well known. But a communications receiver is not a spectrum analyzer and they're not what you hear when you listen to a receiver. What you hear is what Tom describes -- clicks whose amplitude depends on the rise and fall time, and not on the keying speed.

Not only that, Paul, but by approaching the sidebands "from the edge," he has introduced the receiver's AGC
into the mix, amplifying the level of those sidebands. As bandwidth is normally defined as the width of the signal
which contains "x" percentage of the mean radiated power (FCC rules say 99%), no measurement is possible
without including the fundamental as a basepoint. If each sideband beyond the occupied bandwidth contains
0.5% of the power, then those sidebands are -23 dB down from the carrier.

He used a transmitter and receiver in close proximity, so it a virtual certainty that the clicks at the threshold of
audibility are much, much more than -23 dB (6 S-units) down from the carrier. Furthermore, even though clicks
may be present, they occupy a small time fraction of the actual radiated signal further reducing their mean power.

Assuming that the clicks last the full 5 ms rise/fall time of the suggested shaping, and a 40 wpm sending rate, the
instantaneous level of those clicks must also be reduced to .010 (rise+fall) / .060 (time of 1 dot @ 40 wpm) = 17%
of their instantaneous maximum. (And even lower still, considering clicks are an even smaller percentage of
dashes.) That alone makes these clicks -8 dB down in mean power, so that the actual instantaneous power
would only need to be -15 dB down from the carrier for them to be considered outside the bandwidth.

So, let's say that the receiver, in close proximity to the transmitter, was receiving the carrier at only S9. In order for
those clicks to be within the defined bandwidth, they would need to be at a level no more than 15 dB down from
that, which is more than S6 (which would be 18 dB down.) Unless his FT-1000 is seriously broken, S6 is well

beyond the threshold of audibility. If we assume that he heard the clicks at S1, then they were 36 dB down from
the carrier, which places what he heard over 20 dB below what they would have to be to be considered part of
the occupied bandwidth. Of course, with xmitter/receiver in such close proximity, a more realistic assumption is
carrier at S9+20 (+), which places his clicks at over 40 dB below the level they would have to be at to be
considered within the bandwidth.

No, it has a carrier oscillator that is keyed on and off. The rise and the fall of the waveform is almost vertical. I haven't counted the cycles, but it isn't too many hundreds of cycles of the carrier oscillator before it reaches full amplitude.

This would be the same in any rig that shapes the CW later.

>If this is the case, then the test results with 5/40 WPM that you
>previously posted are completely bogus and prove nothing about the
>effects of keying speeds and transition slopes.

No. As I said above, it is exactly the way any rig would behave that shapes the keying in later stages. It does not matter if you shape in a crystal filter at radio frequencies or shape the keying signal modulating the stage. A certain bandwidth will produce a certain shape, and vice versa.

>It is quite obvious that the offset at which clicks are detected will
>be about 1500 Hz due to the +/-1200 Hz from the Tx filter and +/-125
>Hz from the receiver filter, so the test really proves nothing about
>keying waveform shaping.

The same is true in a rig that keys a stage following an oscillator. It matters not one bit how you get the envelope as long as the signal is filtered someplace for bandwidth and the following stages do not add distortion.

If you look up a few postings, you will see Roy Lewallen just posted his understanding and agreement with what is said.

The fact is this, as long as the keying speed is reasonably slow compared to the rise and fall times the rise and fall times set the bandwidth of the signal. It doesn't matter one bit to a receiver if the clicks happen ten times a second, ten times a day, or every ten

years. You will hear the sidebands the same distance.

Roy's way of looking at it is a good one. Once the energy in the clicks decays to zero, it makes no difference at all if sideband another comes along or not. The click bandwidth, since the receiver (unlike a spectrum analyzer or storage scope that stores and analyzes many dots) does not "store" a click or the energy in sidebands, cares less what happened 40 mS before or what will happen in the future.

Every rise produces one click, every fall another, and the bandwidth of those clicks almost always is different. That is what you hear up and down the band, and unless the elements of code are so fast that the flat part of the carrier or zero point of the carrier are so short they rival the rise and fall times you will never see a change in bandwidth with speed.

That is how virtually all rigs operate. That is how all receivers that are not seriously flawed or overloaded operate. That is how our ears and brains work.

I've received permission from W9CF to post his analysis on my web page, and I will do that over the next week. His analysis bears out what I am saying.

So now Roy, Kevin, and myself are all on the same page.

>BTW, is the low click modification simply that the Tx signal is routed
>through a narrow (500 Hz?) CW filter instead of the stock SSB filter ?
>No wonder that the results are the same for both keying speeds, since
>the bandwidth is simply set by a crystal filter.

What you miss is it doesn't matter one bit (pardon the pun) if the filter is before the modulator or after. It only has to be ahead of the antenna and after the key.

It would be very nice to generate the CW and filter it in a 250Hz filter, because then only stages after the filter would have to be linear to prevent excessive clicks. When you filter the keying signal before modulation, the modulator and all other stages has to have the correct response.

I feel better now that real-world bandwidth in the actual application is now being considered. It is the rise and fall that makes the clicks and controls the click bandwidth in a normally operating real-world CW radio system, not the speed.

>what is happening during the rise and fall periods.

Yes indeed.

That argument ASSUMES the filters are set and reset at the bandwidth
required for the keying speed, rather than for the highest keying
speed.

Either that or it assumes the sidebands generated by the rise and fall
do not decay to zero before the next change in carrier level comes
along.

>bandwidth.

I think that is the crux of the problem. I think people have just been
looking at it from the point of something that stores information (dc
response?) rather than an actual receiver.

Because of that, the conclusions while correct for a device that
stores the sidebands, are incorrect for a receiver that only (like our
hearing) works in real time.

Both solutions are right, but I am stubbornly insisting it is how the
real-world receiver works that matters. After all, very few of us use
storage scopes to copy CW.

It is what we hear on the receiver in real time that matters for interference, not what would happen in an infinite amount of time.

>beyond the threshold of audibility. If we assume that he heard the clicks at S1, then they were 36 dB down from
>the carrier, which places what he heard over 20 dB below what they would have to be to be considered part of
>the occupied bandwidth. Of course, with xmitter/receiver in such close proximity, a more realistic assumption is
>carrier at S9+20 (+), which places his clicks at over 40 dB below the level they would have to be at to be
>considered within the bandwidth.

I can move the receiver closer to get stronger clicks, turn on the AGC
with slow decay, read the S meter, and change the speed. The meter
does not change any amount I can notice.

I can turn off AGC and set the gain so I can barely hear the clicks. I
can change the speed, and the clicks do not b get louder....only more
frequent.

Please read Roy Lewallen's explaination,. it might help you follow
this.

Where do you live? Where have you looked? I find, for
example, that Newark have it in stock. Analog Devices
sell direct, though their terms are unfavourable for
non-U.S. customers.

> As far as that goes, where did all the homebrew friendly vendors go

> (at least in this area)?

While nominally an industrial/OEM supplier, Newark have
never refused my money for onesies and twosies, so I would
describe them as "homebrew friendly". Ditto Future. Ditto
lots of others.

I get weird and wonderful stuff from Barend Hendriksen.
They also carry AD9850 and will sell you as many as you
want.

While hobbyist electronics suppliers are indeed extinct,
there are lots of industrial/OEM suppliers out there who
are not averse to small orders. Some even go to some lengths
to accomodate small orders, especially if they come from
hams.

The parts are there. Go get them!

>
> > I find this discussion truly fascinating.

The receiver is a pretty good spectrum analyzer, especially a narrowband CW receiver. Statements to the contrary are not correct. Because of AGC it has a quasi-logarithmic amplitude response. It responds to the spectrum that passes through the narrow filter and delivers energy to the headphones (detector). If the receiver is tuned away from the carrier, it will respond to any energy that is in the frequency band that the receiver is tuned to. That is precisely what a spectrum analyzer does.

If code speed is very slow the spectrum of the signal may just be a function of the rise and fall times of the signal. My writeup in Chapter 17 of the ARRL Handbook clearly mentions this. That writeup is correct in all aspects.

But as the code rate increases, some of the incoming energy that is due to the Morse code sidebands will show up in the off-channel passband of the off-frequency receiver. Simulations clearly prove this fact beyond doubt. This additional energy is a valid signal just like anything else, and it is passed on to the headphones.

If listening tests fail to detect this increase, that does not mean, and from basic principles cannot mean, that the event of the previous paragraph is not happening. If the code speed is increased enough, it will (must) show up, unless something is preventing it.

What is being discussed is adjacent channel interference, where the interfering signal is not heard as a beat note, only its key clicks. If the code speed is increased sufficiently, the interference must eventually show up, unless the rise and fall clicks (or whatever else may be at fault) are so bad that the code speed effect can't be noticed even at high code speed. This is the classical key click problem that needs to be fixed.

Revising the basic principles of signal processing is not the right approach. The right approach is to fix the defect in the transmitter, possibly by revising the shape of the Morse characters, or fixing the parasitic, or making sure that the wave form is not getting screwed up somewhere in the signal path. Maybe the receiver is at fault somehow. Is stray xmtr RF messing up the receiver?

Long history has verified that a clean 5 or 6 ms rise/fall time leads to a clean signal for which code speed spectrum widening can then become a factor.

I nearly forgot to mention that I find the idea of 'disregarding' the space periods and looking only at what is happening in the mark periods to be a very interesting approach to understanding CW bandwidth. I understand what Tom is saying about this 'present' and 'future' thing because it is exactly how I felt about it.

When you transmit AM signals you measure the bandwidth when you are transmitting with the signal present. Nobody thinks of the 'bandwidth' as including the squarewave ratio of transmit vs. receive periods when you are listening to the other station. If you modified the concept of 'bandwidth' to include this second factor (reflecting the time relationship between transmit/non-transmit periods) I don't think anybody would be very interested because it is intuitively obvious that sometimes you are transmitting and sometimes you are receiving.

This is just about how I personally feel with CW signals. If you are talking about the bandwidth that the energy spectrum of transmitted CW signals occupies (as opposed to the bandwidth required for demodulation) then I think you should start by thinking about what happens in the rise/fall times and then talk about what is happening as a result of the relationship between mark/space periods as a secondary issue.

I also just noticed that some of the quotes contain phrases like "identically shaped" or "properly shaped" envelope when describing why bandwidth is dependent upon keying speed. I have not looked at the original documents, but if "identically/properly" shaped assumes rise/fall times defined as a percentage of dot length (so the faster you key, the faster your rise/fall times) then maybe there was no problem all along.... perhaps they were trying to say that "bandwidth increases with (rise/fall times if you assume that these get shorter as you increase the) keying speed."

If I understand Tom correctly, one point he made was that in reality rise/fall times are the result of rig design and generally do not get shorter as you key faster so this is not what happens in the real world.

That's certainly true!

For UK readers, I keep a list of component suppliers at
http://www.ifwtech.com/g3sek/in-prac.components.htm

It doesn't currently deal with the problem of buying ones and twos of
exotic RF devices... though you'd be surprised at what's in the Farnell
catalogue. (I just looked, and they stock several of the AD9830 series
though not the 9850. They also stock a fair range of Agilent/HP RF
exotica including MMICs and GaAsFETs)

All the "Big Three" UK dealers - Farnell, RS/Electromail and Maplin -
are now happy to take anyone's money by credit card. RS are a bit more
awkward to deal with (always have been) and have a poorer range of RF
components so I generally go to Farnell.

The important thing is to be businesslike in dealing with them. The web
page suggests how to go about this.

If anyone in the UK has information to add, or a dealer to recommend,
I'd be happy to include it on the page.

Before posting, i had gone through the information on your site, it is really very useful. Actually what i am trying to design is a simple PLL based VFO using the CD4046 ic(similar to the design by Harry Lythall SM0VPO, http://hem.passagen.se/sm0vpo/conv/syn-info.htm), for this i need a VCO which can be pulled about 0.5 MHz to cover each ham band completely(I have not decided how i am going to deal with the 10m band which needs a spread of 1.7MHz), since the change in capacitance obtained by using common diodes is relatively small I was wondering if i could use FETs instead to obtain the necessary frequency shift. I look forward to your views in this regard.

Thanks everyone for the advice. I think I should explain in a little more detail what i am trying to do. I am involved in the design of a low cost ham transceiver using readily available ics, for hams in india (I know it has been done before, but I wanna do it my way :-)). At present I am working on the VFO, it will be a PLL based design using the CD4046 ic, similar to the design by Harry Lythall SM0VPO, http://hem.passagen.se/sm0vpo/conv/syn-info.htm. I chose this design because it is relatively uncomplicated and the ics are available in india. For this design I need a VCO which can be pulled about 0.5MHz to cover each of the ham bands(I haven't decided how to cover the 10m band which needs a shift of 1.7MHz, i look forward to your ideas in this regard). Since the commomly available diodes (1N4007 etc.) do not seem to give this kind of frequency shift I was wondering if I could use FETs instead (BTW, BFW10/11 are available in india, while varicaps are not), which i have been told have a larger change in capacitance. I shall soon be putting a post about using the TBA120 as a product detector and a balanced modulator (yeah u guessed it, the TBA120 is commonly available for use in TVs while the NE602/MC1496 are not)an idea which i got from a transceiver design from LZ1SE 's site. Looking forward to your replies.

Experiements with TBA120 as converter/modulator/phase detector have
been carried out by a number of German and Dutch experimenters, some
of these notes are published by the magazine Elektor around 1980, some
in the Dutch magazine Elektron (VERON).
Examining TBA120 =SN76600N or SO41P you will see that it is almost the
same as Plessey SL624 (multimode detector) and you can get the same
functions, perhaps inverted phase - it is not easy to judge. But
TBA120 has a problem with distortion, I am not certain how important
this is, also leakage is not as good as for MC1496P, TBA120S or AS has
some feedback capacitors which upset this even more
To understand TBA120 you should read the following article in Radio
Communication, september 72 showing complete details:
TBA120 applications G3TDZ 72- 9-pp592
also these may help
Consumer IC AM-VHF-RX G3TDZ 72-08-516
Consumer IC in amateur design (3) G3TDZ 72-10-664
Consumer ICs in amateur design (1) G3TDZ 72-08-516
Consumer ICs, CA3089/TBA120(455kHz) (2) G3TDZ 72-09-592
Mixer with TBA120 (Balanced modulator) LA8AK radcom 85-11-861
TBA120 Balanced modulator LA8AK Radcom 85-11-861
Mixer with TBA120 (SO41P) UKWBerichte 75-03-185

On http://www.qsl.net/ok1cdj/dubus/index.html you may find some
articles, one of mine is
8504-4 3 109k Using TBA120 for MS reception

I have some more articles on the application of TBA120 published in
this magazine, but they are not displayed on this site. I think the
best solution is to look for which device is the cheapest, probably
MC1496P, and when you know how many devices you need it is easier to
get a low price, TBA120 has built-in oscillator (limiter), but the
oscillator is built using a 2N3904 npn device

TBA120 is a device to be compared with NE604/614

I have also seen my articles on TBA120 published in Yugoslavian amateur radio magazine sometime in 1980's, it was also a similar article about MC1351P as multimode detector in Radcom 1976-77

144MHz RX AM/CW/SSB/FM (1) (MC1351) G8IBR 76-12-900
144MHz RX AM/CW/SSB/FM (2) G8IBR 77-08-600
this is based on the earlier note:
MC1351 FM/AM detector G4BLT 74-06-pp380

IF level input for TBA120 as AM or SSB detector is abt 5mV rms

This is of course true for determining the actual offset frequency.

However, for a simple audible/non-audible decision for various keying speeds with the _same_ transmitter setup, this test is valid, provided that the receiver has sufficient gain so that the equipment noise is audible when no signal is connected to the antenna and that the agc, if used, is taken after the final IF filter.

However, the bandwidth _ratio_ figures between the standard and modified transmitter are not comparable, unless the measurement level is defined relative to the carrier, since the _shape_ of the spectrum may be different in different cases.

>He used a transmitter and receiver in close proximity, so it a virtual
>certainty that the clicks at the threshold of
>audibility are much, much more than -23 dB (6 S-units) down from the carrier.

Using a double shielded cable from the transmitter to a shielded dummy load and connecting a 50 ohm terminator directly at the receiver antenna terminal usually gives quite good isolation.

If the carrier signal is still quite strong in the receiver, say S9+60dB, there is of course a great risk of reciprocal mixing between the Tx oscillator and its phase noise and the LO and its phase noise. In such situations we are not observing a set of narrow spectral lines, but a set of peaks in a floor of overlapping noise sidebands.

OK, but from the other messages it appears as this signal still goes
through the SSB filter, effectively setting the bandwidth. Thus, the
effect is the same as generating J2A, except that there would be no
aliases due to "negative" frequencies in the passband.

>>BTW, is the low click modification simply that the Tx signal is routed

>the antenna and after the key.

I am fully aware of that situation, since I have been using for quite
a while a DOS based DSP simulation package with a limited FFT size, so
I have done all my simulations at base band and then manually
translate the result to the amplitude modulated carrier :-).

Assuming there is a good quality SSB filter (BW 2400 Hz, 2:1 shape
factor at -60 dB), this corresponds to baseband filter (after the
keyer) with a 1200 Hz breakpoint and -60 dB/octave slope (thus -40 dB
at 1900 Hz and -60 dB at 2400 Hz), corresponding to a 10th order
Butterworth filter.

However, when we are talking about click avoidance, we are usually
talking about 1st order RC filters (-6 dB/octave) with much lower
breakpoint frequencies.

Assuming a fixed filter that should pass up to the 5th harmonics at
speeds up to 40 WPM, the breakpoint would be at 80 Hz. Thus, -8.7
dB/octave slope would be needed to reach -40 dB at 1900 Hz or -12.2
dB/octave to reach -60 dB at 2400 Hz. In order to minimise the wave
shape distortion, the Besser response would have to be used,
corresponding to 2nd resp. 3rd order Besser filters to get the
attenuations comparable to those that are obtained from the crystal
filter in the transmitter IF path.

One way to minimise the harmonics in the baseband waveform would be to use a tunable switched capacitor filter (SCF) with a tunable breakpoint and Besser slope. With a dual potentiometer, you could set both the keyer speed and the SCF clock frequency or simply divide down the clock to get the keyer speed.

Using the MAX292 8th order Besser SCF and setting the clock to 8 kHz (100:1 clock to corner frequency ratio) for an 80 Hz corner frequency for 40 WPM and 5th harmonic, the -40 dB point would be at 270 Hz and -60 dB at 375 Hz. Such attenuations would be extremely hard to get with crystal filters in the Tx IF path.

Setting the clock to 600 Hz, would produce a signal suitable for 5 WPM with 3rd harmonic present, the -40 dB point would be at 20 Hz and -60 dB point at 28 Hz.

Unfortunately the MAX292 has only a 100:1 clock/corner frequency ratio, so there might be some alias components when tuned to the lower end of the frequency range. Two cascaded 4/5 order MAX281 SCOff might be a better solution due to the available 401:1 clock to corner frequency ratio.

But on the other hand, why generate a dirty square wave in the first place and then apply a complex filter to clean it up, when you could directly generate a clean shape from a lookup table and run the result through a simple DAC.

All this assumes that the modulator and power amplifiers are linear enough in order to not recreate the unwanted sidebands that have been removed with a great effort.

It's usually risky disagreeing with Laura, but in this case I will. While the AD9850 is a kind of a tough part, there are lots of hobbyist-friendly suppliers out there, and there seem to be more every day.

Besides outfits like Newark, Mouser, and DigiKey, who will gladly take small orders, although their shipping may make really small orders unattractive, there are places like radioshack.com (nothing like your local RS) that have lots of parts and very attractive terms for small orders. And there seem to be more and more pure hobbyist places like Dan's, Baggy Bob's, and kitsandparts. If you're into scrounging stuff for very low cost, there are places like B.G. Micro and Mendelsohn's, who have very odd inventories, but can be very cheap if they happen to have what you need.

The web has made homebrewing a lot easier, and made it possible for all nature of parts suppliers to make a living at what is surely a very small niche.

That is correct.

Like virtually all SSB rigs, except the old Collins rigs that used a
tone to drive the balanced modulator, Yaesu unbalances the carrier
oscillator and shifts it into the passband of the filter.

The only problem is they do not properly shape the waveform, and with
a sharp transition at the top of the rising edge and an abrupt drop at
the first part of the tailing edge...as well as too fast a rise and
fall...the rig has excessve bandwidth.

>However, when we are talking about click avoidance, we are usually

A simple R/C filter gives you a shape like the poor waveshape the ARRL
handbook calls "optimum". That shape will produce needless clicks no
matter how fast or slow you send, because of the sharp changes in
slope at the top of the envelope rise and fall.

That's what happens when you use a single pole R/C filter to limit
keying sidebands. No matter how fast you send, the rig MUST have
clicks extending out a considerable distance in order to produce the
sharp changes in rise and fall times.

Right you are, but the problem is most rigs are NOT properly filtered.
I think much of this problem comes from the engineers thinking that
the bandwidth narrows with speed, or pure unvarnished ignorance,
because it would only cost pennies to correct the problems.

>One way to minimise the harmonics in the baseband waveform would be to
>use a tunable switched capacitor filter (SCF) with a tunable

I tried that with a filter chip, but there were problems with the device I used. It gave a raised sine waveform.

We also have to design a linear modulator and the ALC system have good hang time.

I think Roy Lewallen uses an ALC based shaping system in his homebrew rigs. I am trying to use a multi-pole multi-section filter that I can switch. In a typical transceiver, they could just dump the TX signal through a CW filter to limit bandwidth. That would cost pennies, if anything at all.

>Using the MAX292 8th order Besser SCF and setting the clock to 8 kHz

I'll have to see if that is the device I looked at.

>All this assumes that the modulator and power amplifiers are linear
>enough in order to not recreate the unwanted sidebands that have been
>removed with a great effort.

Right you are. That is what finally stopped me from building an add-on CW modulator for the FT1000 series. I initially thought about lifting the TX IF lead and adding a PIN diode modulator keyed by a lowpass filter of some form. The problem is the ALC system mucked up the waveform. Instead I opted to slow the rise and fall via R/C additions. A little in each keyed stage (there are at least three keyed stages, one before and two after the filter).

But now I'm thinking maybe there is a way to get the 500hz CW filter into the system. Anything has got to be better than clicks extending up or down 1.5 kHz at significant levels!

Anyway, at least some are now considering this from the real-world point of view instead of this nonsense that sending slower reduces the click bandwidth of the real-world transmitter. that's a start. The next thing is to get the ARRL and others to pressure manufacturers into cleaning up these pesky clicks, since no matter how fast someone sends they extend up and down the band the same amount.

> signal is not heard as a beat note, only its key clicks.

You are of course correct. What Tom is talking about is NOT bandwidth, as defined by the FCC or common
usage, but spurious emissions, which are by definition emissions outside of the bandwidth.

I refer to the FCC rules, 47CFR97.3a:
"(8) Bandwidth. The width of a frequency band outside of which the mean power of the transmitted signal is
attenuated at least 26 dB below the mean power of the transmitted signal within the band,"

"(42) Spurious emission. An emission, on frequencies outside the necessary bandwidth of a transmission, the
level of which may be reduced without affecting the information being transmitted,"

97.307
"(b) ... Emissions outside the necessary bandwidth must not cause splatter or keyclick interference to
operations on adjacent frequencies."

"(d) The mean power of any spurious emission from a station transmitter or external RF power amplifier
transmitting on a frequency below 30 MHz must not exceed 50 mW and must be at least 40 dB below the
mean power of the fundamental emission. For a transmitter of mean power less than 5 W, the attenuation must
be at least 30 dB. A transmitter built before April 15, 1977, or first marketed before January 1, 1978, is exempt
from this requirement."

The FCC clearly defines (47CFR2.202) the necessary bandwidth of a CW signal to be "B<INF>n</INF>=BK,
K=5 for fading circuits, K=3 for non-fading circuits 25 words per minute; B=20, K=5, Bandwidth: 100",
showing that they understand that bandwidth is a function of both keying rate and shape.

So if Tom is using an FT-1000, and measuring spurious emissions (those outside of the approx. 100 Hz
necessary bandwidth) of less than 40 dB down from the fundamental (as he MUST be in order to claim those
keyclicks are included in the bandwidth), then he is running an illegal station.

|frequency and hears a click each time the dot is made or broken, and its
|amplitude doesn't change with keying speed regardless of how far away he
|tunes.
|
|The problem is that Tom isn't listening to the signal with a spectrum
|analyzer, so he's not hearing what the spectrum analyzer shows.

Since you speak of frequency domain analysis, you must be talking about swept-frequency spectrum analyzers (SA). I submit that is *exactly* what Tom is using, albeit a very slow tuning one. His receiver has a down converter to an i-f filter/amplifier, that is ACG-controlled, giving it quasi-logarithmic gain characteristic, a detector that loses phase information and a post detection audio (video) filter. That sounds pretty much like many of the SAs that I've used for 30 years or so.

As you well know, swept receivers (SA) have particular problems when looking at signals that are sometimes there, sometimes not, i.e. pulsed signals, which is what is really being discussed here. However, if Tom's receiver bandwidth is narrow enough to separate the PRF lines and the pulse train is coherent and long enough to make the measurement, then his "analyzer" would seem to be up to the task.

> are not), which i have been told have a larger change in capacitance.

I'm not digging out the articles right now, but I don't think the
FETs were being used as variable capacitors. Instead, they were
used as variable resistors, which in series with a capacitor, changed
the overall capacitance. I know Doug DeMaw once wrote about
putting a small value potentiometer in series with a capacitor,
and getting variable tuning that way, and I assume the FET is
functioning the same way. I've seen the same idea suggested elsewhere,
though at the moment I can't think of where.

There was an article in QST in the fall of 1972 about "synthesizing
a varicap". He went into an explanation, I can't remember if
it was valid, about doing it. But basically he used a bipolar
transistor in series with a capacitor, and the coupling capacitor
was set the maximum capacitance.

I'll have to dig it out later.

But the only articles on this sort of thing have been on the experimental
level. I've yet to see anything about limitations, be it capacitance
of circuit Q. The idea of putting a variable resistance in series
with a capacitor to make the latter variable does make me wonder
if there will be deteriotion as the resistance goes up (and hence
put a limit on how much change can take place).

>
>
The key to this is that as part of the FM demodulator, there is
circuitry identical to what's in the MC1496, ie what is now
called a "Gilbert Cell Mixer". You'll see that in a lot of
ICs and the real problem is whether you can access the mixer
without a lot of other circuitry getting in the way.

For instance, the MC1350P IF amplifier has one of these, in
the form of a gain cell, and it could be used as a mixer.
But somewhere between the input and output, there is an
additional gain block, which may not make it useful in
all situations.

A lot of FM demodulator ICs use them. But you have to
watch because a number of different demodulator schemes
have been used in ICs, and not all of them use Gilbert Cells.
And some may be better than others, because if you can find
one where you don't have to go through the limiter to
get one input to the mixer, it probably works out better.

Motorola made a number of ICs for two-way communication use
that had such mixers. The earliest ones had one mixer,
which was used to convert from 10.7MHz to 455Khz, and then
an FM IF strip. I've seen these in cordless phones, which
in North America can often be bought quite cheaply used.
Then there was a second generation of such ICs, that included
a second mixer, for the first conversion. Someone has written
about using them in SSB/CW receivers.

Chroma demodulators in TV sets often use such mixers. But
they have oddball outputs and again the inputs may not be so
accessible. They might be worth playing with, for the simple
reason that they are very available.

One thing worth keeping in mind is that one could make "Gilbert Cell Mixers" with discrete transistors, which one would hope are readily available. They would take up more space, and they might not be as well balanced as an IC (yet, hams got along without ICs for years, so it's all relative), but they'd be cheap. Doug DeMaw did once or twice use transistor array ICs to build such mixers but I'd assume such ICs would be troublesome to get (and maybe not just in India at this time).

Or, you could go for some other sort of mixer. If you can make up the gain, diode mixers can fairly easily be thrown together. Years ago, people even described making toroids out of the ferrite cups in IF transformers.

And there have been all kinds of product detectors and mixers and balanced modulators made with discrete components described over the years. They might be more suitable in a place where parts can be hard to come by. Here in North America, NE602s are common in designs simply because they are common. They aren't necessarily chosen for what they provide, but because you can get them easily and "all the other circuits use them". Unless someone is building some high spec equipment, and you wouldn't be using NE602s then, one can get by with circuitry made of discrete transistors or diodes.

Fig 12.21 in the 2001 ARRL Handbook has a very interesting graph that relates 1) bandwidth, 2) code speed words per
minute, 3) rise and fall time as shown in Fig 12.20 and 4) K values. For DX hunting we want a K=5 which is a little
"harder" signal and therefore occupies a larger bandwidth.

For a 6 ms rise and fall time and a K=5, I see 30 WPM (12.5 dots per second) and a bandwidth of about 120 Hz. Most
of the signal energy lies within that bandwidth. If there is significant stuff outside that bandwidth, we should be
looking for an equipment problem or poor wave shape.

good luck using a 706 for sat work. its prob the worst rig you could use for
that. You should use the right tools for the right job.

Source record: 49789

Hello, all,

A while ago I came across a web page that described a novel reflex receiver, and I am hoping someone can help me find the URL again. I have lost it and tried to find it, with no luck.

What was unique about this design was the way the audio was amplified and coupled in the receiver. It was done in such a way as to not overload any stage. So, the Audio went backwards through the receiver. It had three stages, so the audio was fed into the third tube where there was a large RF signal, but could easily tolerate a low level audio signal. The first stage had low level RF, but lots of audio. It was a complicated circuit diagram and the author went to great lengths to draw this out and explain it.

Anybody out there know of this site?

Thanks in advance,

Clyde KA1CRV

Clyde, such designs were popular in the 20's when the goal was to get as much receiver as possible out of the least number of expensive and fragile tubes.

In the 30's and early 40's, it was the other way around when the number of tubes in a radio was a major marketing point. One company, Midwest, would use 20 tubes in a radio but only about 5 of them were doing anything. The others just lit up their filaments to look impressive!

That was a little before my time, but I remember the same marketing race with transistor radios. The first radios typically used 6 transistors, but soon the race was on. "12 transistor radios" "20 transistor radios" and so forth hit the market amid the usual hype. Like the over-tubed radios of the past, the extra transistors were soldered in but not connected to anything. I imagine that defective transistors were used for this purpose. The government eventually stepped in and required that the extra transistors actually be used. The manufacturers quickly responded -- transistors were connected and used as diodes, with push pull and bridge detectors suddenly becoming popular, and I recall one radio using 8 transistors in push-pull parallel in place of the usual 2 transistor 2N109 output stage. And no more output than a pair of 2N109s would deliver. Guess it's all driven by the philosophy that if enough is good, too much must be better.

5997. Help CD4046 PLL

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-29 23:19:30 UTC
From: amdx <amdx@att.net>
Message-ID: <6Gst7.16357$3d2.1390437@bgtnsc06-news.ops.worldnet.att.net>
Source record: 49794

In an effort to get my feet wet on PLLs, I set up the osc. section.
I used a 470pf and 10k to ground, I used a 100k pot to B+. (9V)
I can vary the frequency over a very wide range. Looks great,
however, the output signal only swings from 1/2 B+ to B+.
Does the CD4000 series need a pullup or pull down?
What do I need to do different?

My end result is to feed a reference signal of 100hz into the Phase
Comparator, set the osc. center freq. about 670khz and use a variable
divider (3,300 to 10,000) to get an output freq. from 330khz to 1Mhz
in 100hz steps. Is this range possible?

Thanks
Mike

P.S. I do have the HCT chips on order.

Actually if you read what I wrote, my rig is corrected. I'm sure many
others are not, and it isn't just Yaesu rigs.

The new TS-2000S is in the mid to low -20dB range for SSB 3rd order
IMD using the ARRL method of dB below PEP.

That would put it in the teens using dB below one tone, the method
most others use.

Anyway, maybe the manufactures think if people send slow the signal
gets narrower.

I have actually used this and variations and it works. The 'range'
cap is by selection after applying the handbook math and it
should be noted the gate is not bypassed so it looks like it is,
as you suggest, working as a resistor. Again, that worked OK
for deMaw.

I have a circuit here for an audio attenuator (stereo) using
the bottom half of a cmos gate (only) in exactly the same way.
Haven't built it but it came from a very respectable magazine.

Stability was not a problem BTW. Pinch off voltage varies from
type to type and it is best to check first.

Cheers.
Murray

I would like to thank W9CF for providing a rigorous mathematical spectral analysis of CW keying at
http://fermi.la.asu.edu/w9cf/articles/click/index.html

The posted analysis is misleading to the layman in presentation, although factual in content. Presenting the data in dB, a logarithmic scale, does not
make it visually apparent where the actual power distribution is. It is quite natural for humans to look at the data presented, and assume that the power
distribution is proportional to the area under the graphs. Due to the logarithmic (dB) vertical scale, it is not.

Let's examine Figure 4, the cases with non-optimal shaping, and the ones which give the most key clicks. I notice that with T=50ms the central peak
rises what appears to be 8 dB over the case where T=20ms.

Visually, it appears that there is about 5% more power in the T=50 peak. Mathematically, the 8 dB difference means that there is approximately
(10^(8/10)) = 6 times as much power in the T=50 peak as there is in the T=20 peak.

Doesn't more power concentrated in a frequency range mean a smaller bandwidth? Let's do a scratch pad analysis...

Looking further, the first sidebands of the T=50 case appear to be approximately the same shape, but 1/2 the width and -16 dB down from the central
peak. One can estimate that they contain roughly 2*(10^(-16/10)) or 5% of the power contained in the central peak. The second sidebands appear at -
22 dB, or 1.2% the power of the central peak. The third sidebands at -27 dB or 0.4%. The fourth at -31 dB or 0.08%.

Likewise, with the sidebands of the T=20 case, the first appears to be approximately -19 dB or about 2.5% of the power of the central peak. The
second -28 dB or 0.3%. The third, -33 dB or 0.05%.

We can see that the power contained in the sidebands is decreasing rapidly. Let's stop there and look at the consumed bandwidth of the two cases,
keeping in mind the definition of bandwidth conveniently given to us by the FCC: "The width of a frequency band outside of which the mean power of
the transmitted signal is attenuated at least 26 dB below the mean power of the transmitted signal within the band."

-26 dB is 0.25%, so as a very close approximation, let's look at the bandwidth including all of the sidebands for each case which have powers greater
than 0.25%. For the T=50 case, that is the third set of sidebands, and for the T=20 case, the 2nd set sidebands. Conveniently, that means that the last
included sideband in each case is approximately equal in size in relation to the central peak, 0.4% vs. 0.3%. It also means that we are including
approximately 100+5+1.2+.4 = 106.4% of the power in the main peak for T=50 and

100+2.5+.3=102.8% of the main peak power in the T=20 case.

Looking again at Figures 2 and 3, and measuring across these sidebands, we can see that the bandwidth consumed by the slower keying rate (T=50)
is approximately 150 Hz, and the bandwidth consumed by the faster keying rate (T=20) is approximately 200 Hz. BTW, T = 50mS = 10 dots per second
= 24 WPM and T = 20 = 25 dpS = 60 WPM. The chart in the ARRL Handbook, which is based upon the FCC "necessary bandwidth" definition for
hard (K=5) shaping, tells us that 24 WPM = 100 Hz bandwidth and 60 WPM = 250 Hz. As noted above, more relative power was included in 24 WPM
case than in the 60 WPM case, so this is an obvious source of some of this error.

Although this simple analysis is obviously not perfect, it does much more closely agree with these sources than those who would claim that CW has
3000 Hz of bandwidth. It also clearly demonstrates that higher sending speeds consume more bandwidth.

Perhaps someone would be willing to do the integration and provide a more rigorous analysis of the bandwidth of each of these cases, given the FCC
definition. It would also be interesting to do the same with the optimized shaping, where the sidebands are even further suppressed.

I would like to once again thank W9CF for verifying what most of us have known all along - that the ARRL handbook is an authoritative and accurate
source of information.

Oops, that's wrong, I didn't include the 1/2 width term, but did double the power because there are 2 identical sidebands. All of the estimated sideband
powers should be 1/2 of the figures above...

> -26 dB is 0.25%, so as a very close approximation, let's look at the bandwidth including all of the sidebands for each case which have powers greater
> than 0.25%. For the T=50 case, that is the third set of sidebands, and for the T=20 case, the 2nd set sidebands.

..which means we include the first 2 sidebands for T=50, and the first 1 sideband for T=20...

> Looking again at Figures 2 and 3, and measuring across these sidebands, we can see that the bandwidth consumed by the slower keying rate
(T=50)
> is approximately 150 Hz, and the bandwidth consumed by the faster keying rate (T=20) is approximately 200 Hz.

..that was wrong too (was actually 150/300 Hz, I only included 1 sideband when looking on the graph for T=20), but no matter, with the newly
calculated sidebands it is 120 for slow keying and 200 for fast keying, which agrees even more closely with the ARRL/FCC figures of 100/250.

6008. Help with 16f84 based PLL synthesizer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-09-30 08:14:12 UTC

Source record: 49705

Hi there,

I am a radio enthusiast and have some small idea on making my
own ham radio equipments. But I am a beginner in PIC stuffs.

Searching in the net, I have found few frequency synthesizer
circuits, that could be used to build a fully modern radio with
LCD display for my personal ham use. But I am facing serious
problems with it, because I am a real beginner in this PIC stuff.

The project I came acroos, uses a 16x2 LCD display to display
transmit/receive frequency. The synthesizer chip is controlled
by PIC16F84. It has frequency up/down pusk switch (like modern
TV erceiver) to change frequency. PLL lock status etc, is shown
on the LCD.

The synthesizer chip is controlled by the 16F84 by I2C bus, SDA,
SCL.

I have the program with ASM file ready with me, but the problem
is, the synthesizer chip (TSA5511 from Philips)is no longer
used, and a much modern chip is available which I want to use.
This is Fujitsu MB1501 chip.

But this chip accepts DATA, CLOCK, LE signal instead of SDA,SCL.
(3 against only 2). Also the timing diagram for both the
synthesizers are different.

Can anybody please help me to modify the ASM file, to be used
with another synthesizer.

I have all datasheet for TSA5511 -&- MB1501 ready with circuit
diagram and the code. Which I can send.

Please help a new beginner.

Thanks a lot in advance.

good info, and MC1310P stereo decoder could well be added to the list,
but I am not sure about using the RC oscilaltor above 100kHz, the
balanced modulator is there, but perhaps rather primitive and again a
problem to achieve good balance, believe it is as bad as TBA120 -
somewhere around 30-40dB, other devices are 15625Hz timebase devices
for TV, but I've only tried such for AFSK generators, MC1310P is also
useful for the same purpose.

A very interesting analysis indeed.

>Let's examine Figure 4, the cases with non-optimal shaping, and the ones which
>give the most key clicks. I notice that with T=50ms the central peak
>rises what appears to be 8 dB over the case where T=20ms.

I was also wondering very much about this 8 dB difference between
figure 2 and 3.

Since a large majority is in the main lobe and the major lobe is 2.5
times wider for the T=20ms and the peak power available from the
transmitter remains constant, thus the noise power density should be
2.5 times smaller (-4 dB) compared to the T=50ms case.

The only explanation I can think for the "missing" 4 dB is that the
T=50ms pulse contains 2.5 times more energy compared to the T=20ms
pulse, thus explaining the "missing" 4 dB.

If this is really the case, then figures 2 .. 4 and 7 .. 9 are
incorrectly labelled as power density (usually measured in W/Hz),
while the actual figures show energy densities (usually measured in
J/W).

In order to convert the actual figures to power densities, the T=50ms
figures should be shifted down by 4 dB.

For a discussion how the varying keying speed affects the bandwidth, I
think it should be more realistic to analyze a series of pulses and
not a single pulse. Since the average power for a specific sequence of
elements remains the same (e.g. 50 % of peak power for a string of
dots), it is more meaningful to compare power densities and not energy
densities.

For calculating the band utilisation (message transmission time x
bandwidth), the energy density figures may be more useful.

RadCom has a 'help wanted' section where people can request help from other members. If all else fails you could put a request there for the missing articles. I often see similar requests in that section. Also, the RSGB might be able to supply photocopies.

William E. Sabin wrote in message <3BB562B7.7C2413BC@mwci.net>...
>If code speed is very slow the spectrum of the signal may just be a function of the
>rise and fall times of the signal....
>

JFYI the original question related to the energy spectrum occupied by the cw signal in space and we were not including any additional complications of what happens when the signal arrives at the receiver. We were just considering whether the spectrum occupied in space does (as one author had suggested) become wider with higher keying speed or not - so I believe we only need to think about what you would see if the spectrum analyzer was tied directly to a theoretical perfect transmitter output.

With an extremely slow test signal (such as an endless stream of 500ms dots) I would expect to see the carrier and possibly sidebands due to rise/fall times but nothing else. (Unfortunately I don't own a spectrum analyzer yet so I can't test this.) I imagine the eyes would be able to distinguish discrete periods when the signal was present/absent - but (1) you wouldn't see sidebands when the signal was absent and (2) the only sidebands you would see with the signal present would be due to the rise/fall waveform changes.

As you increased the keying speed of the test signal, I imagine (excuse me, I'm a hobbyist not an EE) that what is going on in space is exactly the same as what was going on before in the case of the slower-keyed signal.... but now the spectrum analyzer does not have time to show discrete present/absent periods so it tries to express the fact that the signal is sometimes present/absent as a combination of sign curves and we see this appearing on the spectrum analyzer as additional ""sidebands"" around the carrier. (If I understand correctly, these are closer to the carrier than those due to waveform changes.)

I'm still not sure whether this second phenomenon (signal presence/absence) is something I want to look on as a sideband in the same sense as the sidebands due to the waveform changes. It isn't really a sideband. It's just representing the presence/absence of the signal over time and if you do everything sufficiently slowly it disappears. OK - theoretically it's still there but at so low frequency that our brains don't see it that way.

What I really want to know is whether the energy spectrum in space itself takes on additional sidebands as the keying speed increases or whether it would look just the same shape as the slow one (determined only by rise/fall times) if my eyes and brain could sample faster. (Sorry - can't find the right words for what I want to say - does this make any sense?)

I'm trying to explore the idea that if we restrict ourselves to thinking of the spectrum occupied by the cw signal in space, the sidebands due to waveform changes during rise/fall times are real but the sidebands due to keying speed are illusory and depend upon whether you wish to think of the on/off periods as discrete changes or whether you wish to try to express these on/off changes over time as a combination of sine waves. If you prefer the latter, then you should be aware that these sidebands are "present" in the normal sense neither during the mark nor space periods. They simply represent the mark/space frequency.

You say above "if keying is very slow then the rise/fall times determine the signal spectrum" but the question is can we also say "if we look at fast-keyed signals the same way we look at slow-keyed signals as a series of discrete changes then the signal spectrum is still determined by the rise/fall times - but if we additionally start to analyze the frequency of presence/absence of the signal itself in terms of spectral content then we appear to see additional keying-speed-dependent sidebands. These are illusory in the sense that what is happening in space is exactly the same as what was happening in the case of the slow-keyed signal and if your eyes and the spectrum analyzer were able to sample faster then these sidebands would not be visible at all."

If this argument holds then keying speed clearly does not determine the signal spectrum in space in any sense. All that is happening is that as the keying frequency increases the spectrum analyzer and our eyes are having a harder time recognizing the discrete on/off changes and this looks like additional sidebands around the carrier. I think we should have the option of looking at these second ""sidebands"" in more than one way according to which makes more sense for the job at hand.

I also think there are plenty of people who believe that the faster you key the more bandwidth you actually take up in space ("more information = more bandwidth occupied in space") so if there is anything wrong with this I would like you to mention it in the next ARRL handbook. (I think maybe they have taken something out of context and understood it in a way that it was never originally meant such as the "bandwidth" necessary for demodulating the signal.)

Anyway - I'm only a hobbyist - so even if I'm wrong at least I'll learn something.

I've seen all along what the difference is Mark, and never argued that power distribution **within** the width of the sidebands does not change.

But what you miss Mark is that accumulated power from many dots does not matter to either the receiver or the ear. Roy Lewallen tried to point that out, I tried to point that, and others have.

The problem isn't with the measurement, it is with the definition or use of the measuremnent.

The accumulated power of many sidebands that repeat ove time does change and increase, but neither a receiver nor a shuman ear considers that effect.

Why would anyone in his right technical mind define bandwidth with a method that does not describe the effect on a receiver?

Everyone agrees (and has from the start) that over many the repeat of many bursts of sidebands is there is some method of storing the energy in the gaps between the bursts the power distribution will change.

Factually, that makes no difference at all to the receiver because by the time the next sideband comes along ALL effects of the first one are gone....unless your measurement system employs some sort of time storage.

If your rig is a typical modern rig with sidebands from each rising and falling edge extending a couple kHz down and up from the carrier at EVERY dot and dash no matter how fast you send (as long as you move the key and it is not too fast for the system to reach the zero and full power points), then the clicks remain the same intensity and duration per click no matter where the receiver is tuned. The only thing that changes is how often you hear the click.

The problem is never that the truth is misleading, the problem is the definition of accumulated effects of many sidebands is being described to be the effect that the receiver resonds to, and it isn't.

It is a definition error of what clicks do.

My point is simply that the sidebands (clicks) extend the same distance with the same strength no matter how fast you send, within the limits of resonse of the system. Now that many people see this, there is not else to contribute since there is no arguement about the accumulated power that a storage system would see.

The real goal should be to NOT bother people outside the necessary bandwidth, not what a storage system shows.

The absence of a signal creates a sidebands just as much as the presence of a signal.

Consider the simple case, a DC square wave. Let's say it is 5 mS on/5 mS off. The fundamental frequency is clearly 100 Hz. Now change the off time to
10 mS. You will end up with two "fundamental" frequencies, a 100 Hz one (on time) and a 50 Hz one (off time). The same thing applies when modulating
an RF carrier.

My observation (and also in chapter 17) was that in "signal space", not in the receiver, if you press the key and hold it down, a single click is generated that lasts for the brief time that it takes for the signal to go from zero to its maximum value. The spectrum of that click is also governed by the time that it takes for the signal to go from zero to its maximum value. The faster the transition, the wider the spectrum.

A similar transient is generated when you let up on the key. Note that the amplitude of the transient depends only on the rate of change of the signal and not on its direction, increasing or decreasing.

In the receiver, this transient is "stretched" in time by the filters in the receiver.

A good way to test for key clicks is to use this key-down-and-hold method.

Because the receiver stretches the click for a longer time, it can be especially aggravating to the operator. A Bessel response receiver filter greatly reduces the "ringing" of the transient. An excellent way to approximate this in analog design is with a multi-stage 50 kHz narrowband IF amplifier. I have used this approach and it is very fine.

This single click method is one good basis for ARRL's claim that 5 or 6 milliseconds rise and fall time has, by consensus, been a satisfactory number. It is important to make sure that the falling edge also has the required duration and waveform.

Wrong.

Check Fig 12.21 in the ARRL Handbook. This graph relates rise/fall time and code speed to the -26 dB bandwidth. If you are creating clean and well-shaped rise and fall times, the -26 dB bandwidth is given by the graph. If you are not getting that result, then there is a systematic error of some kind.

Receiver-generated ring-out problems are not included in this.

You are correct, Bill. It should be obvious to all that with more power concentrated in the bandwidth, there is less power available
for the spurious emissions (key clicks). The bandwidth for a slower signal will always be less than for a higher signal; one is not
limited to the FCC definition, it applies to any bandwidth where x% of the power is contained therein.

> for the spurious emissions (key clicks). The bandwidth for a slower signal will always be less than for a higher
signal; one is not
> limited to the FCC definition, it applies to any bandwidth where x% of the power is contained therein.

The above is perhaps not as clear as it should be. For a fixed interval of x Hz, more of a slow signal's power will be
found in that frequency range than for a fast signal. This is clearly shown by the W9CF analysis. Therefore, a fast
signal _must_ have more power outside of that range. The inescapable conclusion is that the power of spurious
emissions (keyclicks) increases with keying speed, just as does the signal bandwidth.

Only if one misuses the term "bandwidth" to mean the full range of frequencies where emissions occur at any level is
the bandwidth of slow and fast signals "equal," and then only because they both extend to infinity. Such misuse of
the term has occured on this group, and also occurs in the written conclusions found in the W9CF analysis, where
the statement "[keying speed] does not affect the overall bandwidth" is incorrectly made.

You can disagree with me all you like. Especially when you
raise so many good points.

When people invoke "hobbyist-friendly" and similar terms, the
usual standard of comparison is the situation of the 1950s and
1960s, when, according to legend, electronic components of all
kinds could be bought for near-giveaway prices at every street
corner. This is no longer the case, and hasn't been for some
time.

Somehow, "parts not available on every street corner" keeps
getting shortened to "parts not available". This is utter non-
sense. Check some web pages, pick up the phone, make some
calls. Get amazing parts. Sounds pretty good to me!

The Golden Age of Homebrewing is *now*.

P.S. I found three suppliers for AD9850 in 5 minutes.
If that's tough, thngs can't be too bad at all.

I'm ancient enough to remember those times. I was fortunate enough to grow up a reasonable bus ride away from New York City, and it's famous 'Radio Row'. There was literally block after block of parts dealers.

Sometime in the late 70's I went back to what had been Radio Row. I was extremely disappointed to realize that two huge towers stood where my wonderful parts supply had been. Well, those towers are no more, but that won't bring back Radio Row.

But those days weren't all that golden. If you didn't live near a major city, there weren't all that many places. Back then I suspect there probably wasn't anywhere in BC that had parts. If I recall, Vancouver was still pretty small. There were wonderful places like Allied, that had everything you could want. And radios and TV's were wired point-to-point, making parts scavenging a lot easier.

But there were no credit cards, no phone orders, no FedEx or UPS. Ordering from Allied meant at least a month, probably two, waiting for your parts. And the prices, in the dollar of the time, were very high.

> The Golden Age of Homebrewing is *now*.

This is 200% correct! Not only are there probably hundreds of parts suppliers you can find on the web, the net provides a way to get in touch with many, many like minded folks. And it makes some of the real giants in the field accessible.

There is no better time to be homebrewing, and there never was!

The Handbook artical is obviously wrong Bill if it says what you
claim, unless it assume we are changing the rise and fall times of the
envelope with speed.

Maybe this will help Ram.

Sideband s are ONLY generated when the wave changes amplitude. The
frequencies generated in producing those sidebands relates only to the
shape and time of the rise and fall, when things are changing.

The problem Ram is that people are considerintg the accumulated
effects of many sidebands, when the rise and fall is the actual
problem.

A real receiver does not anticipate future evens that have not
happened, and it does not remember past events because the receiver
has no dc or low frequency storage. It also "sees" a few hundred
hertz window,

So what happens in a system that stores and resolves very low
frequency energy, like the few hertz is meaningless if your question
is what it sounds like on a real receiver as you tune across the
signal.

The math used is absolutely correct when the repeat of many bursts of
perfectly timed repeating symmetrical sidebands are considered over a
long period of time, but not in a real system of CW with a real
receiver.

>With an extremely slow test signal (such as an endless stream of 500ms dots)
>I would expect to see the carrier and possibly sidebands due to rise/fall
>times but nothing else. (Unfortunately I don't own a spectrum analyzer yet
>so I can't test this.)

A spectrum analyzer, when the bandwidth is narrow requires many very
slow sweeps. It store each energy burst that makes it through the
filters (and the filters will have a large rise and fall time because
they must be very narrow) so you do get the picture you would expect
if the system responded to dc or near dc.

The problem is receivers and our ears do not work that way. It workss exatly the way your intuition is telling you it works.

The receiver, and our ears, hear a click ONLY during the rising and falling edges. Since neither the receiver or our ears stores any energy between clicks (assuming bandwidth is wide engough to all copying of the CW being sent) you hear two clicks that can be and virtually always are different characteristics for each element of the CW.

As someone sends faster, you and the receiver simply hear more clicks per second. The frequency spread is the same if the guy is sending 2 WPM or 40 WPM, as long as the response of the system rise and fall is much faster than the length of the shortest element.

The response HAS to be like that, or you couldn't copy the CW.

1.) A sideband group is only produced while the level is changing.
2.) There has to be a large time that passes between those changes.
3.) There is no storage of those sidebands in a normal properly working CW receiver or in your head.

Because of that, any analysis that includes the repetition of those sidebands or measurement that accumulates them does not apply to the question you are asking.

Speed would matter if you were asking about the accumulated power in the sidebands for a given period of time that includes many elements (dots and dashes), or if the on time or off time was nearly the same or faster than the rise and fall times, but that is the only time.

73 Tom

The absence of signal does not create sidebands. Only a change in
level or frequency creates sidebands.

Neither the steady on time, nor the steady off time, creates any
sidebands.

Hello everyone

I am looking for some freeware to draw schematics that can be exported to BMP/GIF/whatever..
Don't get me wrong, I do NEED need some kind of hi-tech Eagle / Protel / Utlimate / PSPice software to draw schematics in order to do simulations or to design PCBs afterwards.
I just want to draw visually nice basic schematics (resistor, transistor, diode, logical gate...) to use in educational documents and on my website.

Anyone can help?

Greetings,
Franki ON5ZO

> envelope with speed.

It isn't "obvious" to me. I am looking at that graph right now and it says exactly what you suggest. At slower code speeds a longer rise/fall time is recommended in order to get the narrower bandwidth. If the rise/fall time is set for a faster code speed then, if we actually send at a much slower speed, the spectrum set by the rise/fall time may be wider than we would like. Someone has mentioned adapting rise/fall time to code speed. Not a bad idea, I suppose.

But in actuality, if the equipment at xmtr and rcvr are clean, this whole problem is a tempest in a teapot. If the rise/fall is set for 30 WPM and K=5 that should not cause a problem for anyone. Fig 21 says the one-sided 26 dB BW=120 Hz. The crucial trick is to be sure that the spectrum falls off rapidly beyond the 26 dB BW. My computer simulations show that this is not difficult. That is where good circuit design comes in. My writeup in Ch 17 suggests one method to do this: use sinusoidal rise/fall waveforms. I have used this idea in frequency hop spread spectrum gear.

Another thing is the receiver. Any rcvr that uses narrowband audio freq DSP filters has a problem in which the out-of-band undesired sig is doing violence to the stuff that is ahead of the DSP filter. That presents some very tough design problems.

Your friend,

Bill W0IYH

You're a freaking idiot, Tom, and a pedant to boot. I'll say this one time, and one time only. The frequency domain consists of amplitude AND time.
Signal level defines the amplitude, for a square wave as is being discussed, the on/off periods define the time.

Source record: 49734

I have looked at their website, and they have a Reference Manual on line for their 'MidRange' MCUs, but what about the lowly 16F84 and siblings?

Am I not looking in the right place, or what? All I can find on the low end MCUs are the data sheet, which doesn't tell what how the things work.

When I do a web search on '16f84' I get a gazillion matches. Since I only have an hour for lunch I can't look through all of them. Does anyone out there in homebrew land know some web sites that discuss the inner workings of the 16fxx series? I am particularly interested in those devices that have a USART and A/D converters (besides the 16F84 itself).

Another question on the A/D converters built into the MCUs....

I have an application in mind that requires very tight control over when the analog inputs are sampled. The 2 or 3 inputs will have to be sampled in a burst (ch1,ch2,ch3,ch1,ch2,ch3.... up to perhaps 8 or 16 samples each). How fast isn't as important as knowing that the sample rate is constant. What I have in mind is to use either an external interrupt or internal timer to tell when the A/D inputs should be sampled. Is the interrupt operation and instruction timing dependable enough to allow this?

Of course, if the instruction timing is dependable enough (using an external crystal clock) there would be no need for an interrupt---just stay in a tight loop grabbing samples.

My alternative is to use external A/Ds with the 16F84, but I would prefer doing it all in one chip.

You didn't read the fine print. 16F84 is a mid-range chip. They are grouped by the size of the instruction words. Low end is 12 bits, mid is 14. Most designs you see use 14 bit chips like 16f84 or newer versions. Download the Product Line Card to help you decide what chip you want. There are better chips now than the 16F84 and can be had cheaper too. Look at the 16F627, 28. They can be used without an external clock resonator. The 16F8xx chips have many features built in, including ADC in most.

So the Mid-Range Reference manual is what you want. You still will need the data sheet for whatever chip you decide to use. I'd recommend a tutorial of some kind to get you started. The Easy Pic'n book is one. I'm sure you can find one on the web but I don't have one to recommend.

I never use assembler. I program in C. I use CCS C -- http://www.ccsinfo.com/picc.shtml
I think you can start with the mid-range command line compiler for about $100. You can use assembler and MPLAB but its much harder to get results this way. CCS C sets up lots of the things for you like ADC or serial ports. Only takes a few lines of code to use these features in C.

There are internal timers that can be used either by polling or interrupt. I've only used ADC once so I can't comment on latency, but I suspect you can do what you want on the chip. A loop in intructions should be repeatable time-wise too, as long as you don't need to handle ranbdom events. Remember that the 16F84 doesn't have ADC. You will have to choose a different chip.

Any good vector drawing program will produce nice schematics. I use
Kontour on my Linux box. SmartDraw for Windows and ClarisCad for the
Mac are good candidates for the job.

You could use one of the standard programs like Eagle CAD. I
prefer to use Kontour because it gives me complete control of
the final appearance of the schematic. I really hate the look
of some of the library components in Eagle CAD, especially the
transistors without any circle around them!

Newark has no minimum order, but it must be $25 or they charge a $5 service charge.

I checked Analog's budgetary price, and it is $15.95. I am sure I could find $9 more stuff to buy, or I might even buy
two of the AD9851BRS. (Hey, what a way cool part! I can't wait to use it.)

Mouser has no minimum order at all, fyi. Doesn't carry Analog Devices I beleive, though. Mouser was founded by high
school physics teacher who just wanted to buy some resistors for his students, and could not find a place that would
deal with him.

Ed,
I know your website and I knew you have these fantastic looking schematics.
It's those I had in mind.
I normally draw my designs quickly with Ulticap, so I can easily make the
PCB from Ultiboard. But these don't look half as good as yours. In fact
they're no good from an educational point of view, nor from a
troubleshooter's point of view (you know, how a schematic "feels").
I also tried the "screendump" trick and importing it into a drawing
software - but no good either.And unfortunately there are no export filters.
The problem is: I don't want to put in too much time (because I have none
hi) in making a component library myself... That's why I didn't draw 'm in
(let's say) CorelDraw of something like that.

I think I'll slightly disagree with Rex here.

The MPASM is a very nice IDE, and it's free. The choice between assembler and a compiled language like C is very much dependent on where you came from and what you intend to do.

If you're a programmer, chances are you are going to be a lot more comfortable in a compiled language than in assembler, and for this purpose, C is the best choice, IMO, because it's basically a minimalist language.

However, if you are more comfortable with logic design, chances are the assembler will be easier to learn and make more sense.

Since these parts are pretty short on resources, the absolute control assembler gives you is also an advantage. The 16F84, for example, only has 1024 program locations. With assembler, every single one of those locations is in your face, so you are far less likely to waste them. And if you run out, you know exactly the cost of sacrificing one feature or another.

Also, in cases where you want to sample multiple data points and time matters, and you don't have the trivial case of having only one path through your logic, you can control the time of every path with assembler. That's not really practical in C.

That being said, unless you are quite adept at decomposing a problem down into tiny pieces of the sort you could solve with 7400 series logic, you may find it maddeningly difficult to get anything done in assembler. It does take a certain way of looking at the world, and I'm not convinced that everyone can find it easy.

I personally tend to view C as my "native language", but for the sorts of problems I apply PICs to, I find assembler far better, and see no productivity benefit to doing it in C, in fact, quite the contrary. But I've also programmed in the assembler of perhaps a dozen or two different machines, so assembler isn't exactly alien to me, either.

As far as the MicroChip website, download the spec sheet for the part you want to use (for the 16F84 it's http://www.microchip.com/download/lit/pline/picmicro/families/16f8x/devices/16f84/30430c.pdf). Every instruction is described there. For the 16F84 there are only 35, so it's not so hard to learn. If it makes sense, download the IDE and the reference card (which is just a time saver - everything in it is in the spec sheet for the chip.) If it doesn't make sense, go get a C compiler.

Is Mark possibly drawing some parallel with the fact that the spectrum of a unit impulse is infinite in extent and remains defined even after the zero-time instance of the impulse?

This would suggest that a signal that once present but now absent in the time domain has created a continuous spectrum of undefined time duration - ?

Or is he remarking that the transition from signal to no-signal creates sidebands which are associated with a phenomenon in the time domain which is in the past?

Sorry but statistical signal processing grad courses at MIT were taken over 45 years ago and a lot has been lost over the years . . .

Source record: 49648

To each his own, but I NEVER solder thru those darned holes. Two reasons:
1) I have found that when used (put on and removed) there is always one
teensy little wire that will get loose and short the thing out--I've
repaired many
a "mysterious" short where the braid was tinned and soldered thru those
pesky
holes, 2) Many times, once soldered in this way, it is impossible to remove
the
connector and re-use it--OK< I know, I'm a cheapskate.

What I do is to remove the outer covering needed to reach the front end of
the
PL connector. Then I carefully unravel the braid and fold it evenly back
over the outer cover. Then I force the adaptor (if needed for RG8X, or
RG58) over the braid. This makes for a tight fit, and I only have to solder
the tip! For RG8,
or other large coax, I just place the body of the connector over the braid
and
"screw" it on over said braid. Before you say WHAAT?--Is this guy NUTS?--
there IS an advantage, or two, in doing this. First, it solves the problem
of those darned little wires breaking and finding their way down to the
front and
shorting out the thing. By folding the braid back UNDER the body, or
adaptor,
it increases the distance between the "hot" (+) and ground (-) so that, even
if
a wire or two separates, it will do it right at the point where it is folded
back,
and because of the increased distance, it cannot get to where it can do any
mis-
chief. The second advantage is that it is quicker! Finally, again
regarding shorts, "sometimes" that solder can flow TOO much and get down to
the business end of the PL connector, again causing the job to be done over,
OR
having to throw the PL away. Believe me it, DOES work! I've been doing it
this way for 30+ years. Of course, there's no real "right" way to do
this--do it
the way that works for you.

Source record: 49649

But in our respective societies, you are free to barter your skills for whatever
wage the market will bear. You are free to seek out an education, and, for a determined individual, there are innovative ways to come by the financing necessary to achieve higher education. In controlled societies, such as the former Soviet Union, you were often TOLD what job you would do

Here in America, my own father was the son of poor, uneducated farmers. His calling in life was as a minister. He had nothing to barter except his bare hands
and a willingness to do what was necessary to get a good education. He left home at the age of 16 to finish high school at a place called North Greenville
Academy (South Carolina). At this school, he plowed with a mule, harvested crops, and fired the school's boilers in exchange for his high school diploma.
The school later expanded into a Junior College, and he continued there in order to obtain his goals. This was during The Depression (1930s). He then went to New Orleans in 1937 to complete his college studies, again, working various jobs in order to attend school--sometimes at night, or working as a night watchman depending on his class schedule. After this, he was ordained as a minister by his home church, and began to serve a small congregation in southern Arkansas. Moving to North Carolina in 1953, he took courses at Emory University, Limestone College, and eventually, Southeastern Baptist Theological Seminary to get his Bachelor of Divinity degree while pastoring churches. In his 50s, he returned to SBTS to get his Masters. None of it was easy, and it wasn't to get a BIG salary. Hey, when I was a kid, and Dad was pastoring small country churches, we often farmed on the side and raised chickens to make ends meet. We never went hungry, we were warm and reasonably comfortable. And now I appreciate that country life of simplicity
and hard work, although it didn't dawn on me as a kid having to plant beans and "taters" when I would rather be playing. Those days spent farming, plowing
with a John Deere tractor, and gathering in hay were wonderful life lessons in
that I could use as I grew up--exactly what Dad wanted for me.

The point is that those people who have become successful, well, most of them
became that way, not through accident, but because they DID work hard to get there. There will always be envy of those who sit in offices and "push" pen-
cils. But those people often have more pressure and have to make difficult decisions that can make or break a company. It isn't all that easy at the

"top",
either. And I am not one of those, if you think that is the reason I raise
any
defense of them. I spent my working career in the railroad industry doing
everything from sweeping floors, to station agent, to copying train orders,
to
working in a repair shop. Those jobs often required decisions that could
affect,
even kill, others. Yes, they paid fairly well, but the knowledge that one
could
accidentally put two trains in the same block on the same track was a
sobering
responsibility. Copying a train order from the dispatcher, and then being
called
by the train affected only minutes away from your station could put your
heart
in your throat as you desparately ran from your office in the glare of his
head-
light in order to hand up his "flimsies". To delay a mainline "hotshot"
would cause some very stern questions from the Trainmaster, or, at worst, a
10 day
suspension from your duties! Those "high-paying" jobs had some very
difficult
stresses! Believe me, the pressures endured were only partly offset by the
pay.

This is beginning to sound like the sound of one hand clapping. If the absence of a
signal creates sidebands, what is the spectrum of total silence? Of a single dot? Of a
mixed, random collection of dots and dashes? Mark is treading on metaphysical
ground. I'm going to tell my Zen-master friends they'll have to learn Morse code.

By the way, can anyone tell me of another periodic signal, besides total silence and an
unvarying, infinitely long in terms of time, sine wave that doesn't produce either
harmonics or sidebands? I'm sure some of you must know of such.

And now it's my turn to ask a MicroChip (or other vendor) question.... I have looked high and low for a MicroChip part that has both an A/D and D/A. I don't need much accuracy as the application is for monitoring of and control of the voltage applied to varactors in a (hopefully) automatically tuned tuner once the operator specifies frequency.

Can anyone point me to a device that has both A/D and D/A?

You can obtain a significant increase in linear power output, up to at least 144MHz - say 450-500W per tube (by the same standards of linearity you could only get about 250W out of a 4CX250B).

But this requires more than changing grid bias voltages. To get the extra power output you must increase the anode voltage from 2000V to 2500V on-load. Efficiency does not change significantly.

Drive power requirements will probably decrease, and you may have to use loading resistors on the grid.

I suggest you try Harry Lythal's website. He has schematics which you can use to draw circuits by cut and paste. It is really easy to use, and you can make your own symbols if you wish.
Here is the URL : hem.passagen.se/sm0vpo/

Franki
check out latest issue of QST, you have exactly what you want there! A
library of components for Corel Draw. They are exact replicas of the
way schematics are drawn in the Handbook and QST.

It appears to be downloadable from the ARRL website.

Cheers

Thanks for the hint!
I'm waiting for QST to arrive, I only became ARRL member (to get QST) last month, so this should be my first issue.
I downloaded a ZIP-file containing CDR files with symbols from the ARRL website, but unfortunately they were created using a new version of CorelDraw, I only have access to an older version (v7 I believe).

We'll see where we get...
Tnx fr info!

The files I found yesterday were v9 only but now with your message I looked for a more recent file on the ARRL site, and in the QST-files index I looked for the 2001-version.

So I found a new version of the zip file, but this time they added the files for Corel v7+v8+v9. I guess I was not the only one with a compatibility-problem hi.

This is really what I need so thanks a lot!

I thought the ring was there to indicate that the part was discrete?
The times I have seen (in educational/ham publications) ringless
transistors was when they were part of an IC (darlington xistor, op-amp
schematic, etc).

You're actually much closer than you may think. In examining on/off modulation, it's a yin/yang situation, without the off periods,
the on periods are meaningless. As such, it is equally valid to study either. One can picture sending morse code by holding key
down for a while and releasing (generating silence) for dots and dashes (inverted morse?). Such a modulation would have the
same bandwidth requirements as traditional code. With traditional morse code, lack of carrier conveys information about letter
spacing and word spacing. The spaces are an intrinsic part of the characters themselves.

Shannon tells us that information consumes bandwidth. There is simply no way around it. The more information you send, the more
bandwidth you need (with a given s/n). Information is sent by the spaces, and they consume bandwidth (i.e. generate sidebands).

??? ok

I've written lots of code in assembler but not on the PIC. If you spend the time you can develop libraries of functions that let you be productive, but that's basically like using assembler as a high level language.

If you really have an issue where size or timing is critical then I agree -- go to assembler, at least in parts. If you never have done it, there are lots of reasons to be at least familiar with assembler. We all should know the basics for the case where you can debug the output from C if there are difficult strangenesses.

A decent C compiler writes code that is pretty efficient. You can learn tricks that make it work even better if necessary. I'll go to a bigger part before I'll take the time to go to assembler unless there are cost factors like thousands of chips. I think we are typically talking onesies to tensies in this forum.

This is sort of a religious argument and I think I'm done now. Do whatever works for you. Personally I never touched asm on the PIC because I've been there and done that. I have looked at compiler output to understand exactly what was happening when things weren't working as expected. That is a good reason to know the instruction set. If you have never written in asm, its a good learning experience. In a critical situation it might be the best answer, but I haven't seen a need for that in a long time.

For the PIC asm is cheaper -- totally free tools. If that's the deciding factor, fine. You have to spend something to get a chip programmer. I'd recommend getting a C compiler too.

Source record: 49662

Hi
while trying to evaluate several receivers based on published specs I realised I do not fully understand how a FM receiver works...

FM improvement = 10log(3B^2) where B is the modulation index seems to be the rule of thumb (if anyone could show how to come up with this formulae??)

Sooo whats my problem?
It seems as if to gain this improvement I need to filter the detected signal as to bandlimit to moulation bandwith i.e. reduce noise.
Nowhere in my textbooks does anyone show this, they just present the curves teling how the (S+N)/N varies over various moulation indexes.

At first I expected that some of the improvement was due to the precceding limiiter but, no. Accoriding to one source a good limiter only gives an improvement of 1 dB or less.

Is the FM improvement all due to the post detector filtering OR is some gained by detection and some by filtering and in such case, how?

Any good reading on the subject??

Why spend $100 when there is plenty of free stuff on the Web?

I'm not afraid to use assembler. I have programmed in assembler for
the IBM 360, PDP-8S, PDP-11, TMS9900, 8080, 6502, and 6800 (the last
two hand assembled!). I also used to design with 7400 series logic.

I think that in order to get the tightest possible loop for sampling
the A/D I would have to use assembler.

Jim,

The questions you have are answered in the reference manual. It's a 3.5MB pdf file.

http://www.microchip.com/0/lit/pline/picmicro/refernce/midrange/index.htm

Or you can call/email Microchip and they'll send you the CDROM for free.

You can also download individual sections of the reference manual:

http://www.microchip.com/0/lit/pline/picmicro/refernce/midrange/midsect/index.htm

This took 20 seconds to find on the Microchip web page :) I guess it helps when you know what you're looking for...

For the most part, operation of all the midrange parts are so similar as to be identical, the difference being what peripherals (ADC, timers, USARTs, etc) are included. I personally prefer development with the 16F876/877 chips since they have nearly all the peripherals. BTW, Microchip is now selling the MPLAB-ICD for $99 which is a pretty good deal. Develop on the 16F877 and you can downscale to whatever processor you want.

For your ADC question, you can't simultaneously sample multiple inputs, the same ADC is shared between different input pins. There is a minimum time between samples specified in the literature which will determine your maximum sample rate. This also means that if you're sampling multiple channels you must wait the full ADC delay between channels as well. There is also a "gotcha" that you have to look out for, you must insert a delay at a particular place in the sampling routine (been so long since I wrote my ADC routines I can't remember exactly where it is...) or you'll get erroneous results.

You can also trade off resolution and sampling time. For example, if you need less than the full 8 or 10 or 12 bits (depending on device) of resolution, you can decrease the sampling time. This is spelled out in the literature.

You can accurately control the duration between ADC samples by using one of the timers set to generate an interrupt on overflow to call your conversion subroutines. Also, if you're going to use 10 bit or greater resolution, it's a very good idea to put the device to sleep during the conversion, particularly if you are using the internal ADC voltage reference.

If you've never worked with PICs before, I suggest you get a copy of "Easy PIC'n" and other books in "PIC'n" series from Square 1 Electronics.

Sorry, Microchip PICs don't include a DAC. You can use PWM if you're looking for a steady-state DC output or low frequency AC.

I see an advert in a recent Circuit Cellar INK from Cygnal for a 25 MIPS 8051 with 12-bit ADC and DACs. www.cygnal.com

I know of only two PIC models that have D/A converters: the 16C781 (1K program memory) and 16C782 (2K program memory). And they're both "future products" - in other words, you can't buy them yet.

The usual way to get simple D/A capability is pulse width modulation of a standard output. If you need something with more resolution, or don't have the CPU cycles to spare for that, you can easily hook up a DAC; either a parallel one for speed and code simplicity, or a serial part to minimize the number of output pins you need. For example, the K2 uses a Maxim MAX534 quad 8-bit DAC.

You are entitled to your opinion. If you take a look at
most books and magazines, including the ARRL and RSGB books,
you will find that there are a lot of 'newcomers' out there.

I recommend that you find the book on modulation theory written some years ago by Dr. Elie Baghdady. I took his Advanced Modulation course at MIT during my grad school years there, and it was concentrated on FM and applications.

I feel certain that his detailed analyses will answer your questions, and many more!

I have been considering making a homebrew ssb transciever to work 20 meter psk31 off a laptop. I'd use it for hiking and camping, so portability is a factor. Anyone know of a good candidate design?

Mike,
thank you for taking the time and answer!
But frankly I do not agree to that the limiter is really giving me the
FM improvement!

I find more and more evidence that the post detection filtering plays
a key role here. Apparently it is vital to have the post detector
bandwith match the modulation bandwith i.e. for exampte 300-3000 Hz or
the full baseband will detoriate the s/n out.

BUT I have yet still to find out if this is the sole contributor to
the FM improvement?? (Not the capture effect)

Hints and/or comments are very welcome

Georege,
thanks for the tip! I will try to find the book!

In the books I've checked so far has not presented the details, just
showing the usual graphs and draws the detector as a squar box, not
explaining what exactly each sub-block does to the signal
processing...

Cheers

hehe - we've been to a lot of the same places!

One caution ... all those machines are von Neumann architecture machines. The PIC is a Harvard architecture machine. Until you get your head around it, certain things can be surprisingly difficult.

> I think that in order to get the tightest
> possible loop for sampling the A/D I would
> have to use assembler.

Well in principle, but you're not writing a word processor here. Most PIC applications tend to be kind of small, and although the PIC isn't blindingly fast, it's usually fast enough. And as Rex points out, C compilers can deliver awfully tight code these days.

On the other hand, if you are comfortable with 7400 logic, then chances are, the assembler will be at least as productive for you as a compiler, assuming that your application is your typical embedded controller sort of thing.

Rex does have a point about compilers saving time. In fact, I generally counsel folks to avoid assembler at all costs. But I find that for the sorts of applications I apply the PIC to, it generally seems to work out pretty well.

Rex mentioned the idea of building up a library, and thus using the assembler a lot like a high level language. My applications tend to be pretty small and rarely is there much opportunity for code reuse. I do have some routines I re-use to operate the LCD, and also for sending Morse (sometimes I use Morse output when I don't want to invest an LCD) but that's about it. Stuff like wiggling an output or reading a button are so simple that it's easier to write the two instructions, and logic beyond that tends to be specific to the application.

If your apps are more involved, and especially if there's any amount of math to do, you will save a lot of time with a compiler. There are BASIC compilers around as well as C, but I would really be worried about the performance of them. I don't think that performance would be much of an issue for C except in cases where you are counting cycles, and I think C

would be pretty painful there.

MCHP has an application note which covers this (if you don't need a lot of acuracy). Use PWM to charge a capacitor, capacitor in turn feeds a high impedance device like an op amp. You probably want to low pass filter this and you have to periodically recharge the capacitor. MCHP must have 30 pages of apnotes by now.

but 10 bit serial DAC;s are so pervasive...

I find it easier, neater, narrow (10 mil) lines using the "whole page" avery labels, positive PCB material, sodium hydroxide developer etc. I just don't find the iron-on to work as well, or as repeatably. The other thing about Avery Labels is that if you are careful in removing them they can be reused (they are a little expensive, but less than the iron on materials.)

Some folks have reported that the fused toner on regular laser print paper works also.

Experiment and keep notebooks!

You don't want much, do you?

A quick look at the downloadable files at the ARRL's
web site suggests that they haven't (did you look?).
I've seen AD9850-based stuff in the amateur press.
But not AD9851.

Why AD9851? Other than the fancy clock multiplier?

The AD9850 and AD9851 are really the same part except for the x6 built
into the 9851. You can drive the 9580 to 200MHz easily.

I have a lot of blank boards for our DDS6m (uses an AD9850) if someone
wanted to experiment. Never sold this as a kit because I didn't want
to deal with the surface mount soldering problems.

If you can write 68HC705c4/8 code, you can use this board. Of course, you
are welcomed to buy the complete product. ;-)

Nice to use a low frequency clock source. Overall the performance is about
the same.

Look up Collinear antennas. Thats what many people use a 6 or more db collinear antenna. You can make it out of stacked half wavelength of coax pieces. There is some info and projects in AC6V.com webpage under antenna projects.

In many other countries they sell collinear antennas for people in rural areas and they work well. But in my opinion if you dont feed it with at least LDF450 or better you waisting your time. The losses in crap coax will negate the gains of the antenna.

Good Luck

Laura,

I will admit, I had posted before checking the ARRL site, but I asked here because I have, at times,
found the ARRL site not as useful as I wish. I would like to be able to get to past articles on the
site. I was certain that folks following the thread could quickly point me to the definitive article,
if it existed. Thank you for the un-needed flame.

I focused on the AD9851 because I read the thread and gathered that it was a better part, and likely
lower in cost, and on many applications better. According to the data sheet it is nearly software
compatible.

I am sorry that I angered you in my request.

Look up

Somerset Range Kits in the UK. They make one transceiver kit called the Langport. Anyway they have a web page. If you have trouble finding it email me.

They make some superb monoband SSB transceiver kits. They also have upgrade plug in modules for other bands. Its a digital radio by the way. It makes far more sense than something like a Yaesu FT817 which has a junk receiver and consumes too much current doing nothing.

The SGC 2020 would also make good radio, likwise TenTec with there small monoband radios. I have heard so many conflicting reviews of the SGC, that i will buy one and test this radios receiver myself. I cant believe its as bad as some say it is.

Good Luck

IMHO, the schematic graphics that Popular Electronics magazine used in the 1960s is still the definitive pinnacle of layout, balance, and proportion. The style used by the ARRL handbook (at least the several old editions that I have) is OK, but the resistors are a bit spindly and anemic for my taste(!) But the European rectangle for resistors is just to abstract for my taste. No offense, those of you in RightPondia!

Let me know if you do get those 9851s; I've got a pretty good DDS design, with schematic, board layout, and code for the 16F84. I can't take credit for the control code; Jeff Woods is the guy on that one!

Anybody who is interested can feel free to contact me for design details on the 9851; I will make this information available to you free of charge. I have created .gif files for the schematic and board layouts. I have a text file for code that controls a 16F84, and a hex file of the code, if you don't have a compiler. This latest version of the code allows you to use an Optrex type of display that uses the Hitachi HD44870 controller. You have 8 tunable memories, selectable tuning step size from 10Hz to 10MHz, and user adjustable I.F. offset. The picture that Dale Parfitt has posted of the PG150 receiver is the culmination of this design.
Once again, I can't take credit for the cool code; Jeff Woods is the fellow that did that! I've got a philosophy about these things; when I make a cool design public, I am not saying "look what I can do", but "look what you can do!"

Well have purchased solder sucker and have also purchased solder wic... With a little practice i am now able to clean up excess solder and melt the paint off resistors and burn plastic chip holders.... So far i have not tried to remove any of the actuall chips that i want....Funn that i am spending all this time and effort to remove a 3$ Canadian 556 timer... I think it is more the principle then the cost involved... But i will still persist... i can't seem to get all the solder out of the socket holes and everything seems to hold firm... Except one resister lead i managed to get clean... Time and heat whould have definately melted a chip :).....if i spread out the end of the wic it pull solder better? With the sucker i can get all surface solder but there still remains just a little bit left in the joint holes.. Any ways enough of my rambling 73 kc7eip

These kinds of rules are a bit problematic if it is not known what
kind of assumptions are used and if these assumptions are realistic.
Typically such assumptions (simplifications) are valid for a very
specific cases and do not apply when used outside the original range.

For instance defining the required receiver IF bandwidth is
problematic, since especially for higher modulation indexes, it is a
question of how many sidebands to include into the IF passband.
Cutting out too many sidebands and the audio distortion will increase,
so you have to set some distortion limits for these measurements.

>Any good reading on the subject??

In "Microwave mobile communications" by Jakes (New York, Wiley 1974)
about ten pages are used when deriving how white noise behaves alone
in an FM detector :-). In other chapters the baseband noise
distribution and the effects of pre/de-emphasis are analyzed as well
as calculating SNR in various fading conditions (mobile flutter). This
is a very interesting book if you are working with UHF and microwave
FM phone repeaters.

Paul,
thanks for the tips!
Maybe I need to clarify slightly....

The basic question is: What gives the FM improvement?
Looking at a rx lets try to reason around it for a moment.
Carsons rule state that 98 percent of the energy is preserved if we stick to 2(maxmod freq+dev freq) i.e. 2(3+5)kHz or 16 kHz bandwith for a typical narrow band FM signal.

When measuring a receiver lets try a 1kHz test tone. We still have the 5 kHz devation and receiver bandwith somewhat suboptimal.

The noise on the other hand hits the demodulator with full 16 kHz.

Here is the tricky part, what is the distribution of the demodulated noise? If I have a LPF after the detector that cuts off at say 3 kHz allowing for the max mod freq my simple formula
FM improvement=10log(2((deviation/max mod freq)^2) shows 9.2 dB. But if I choose a LPF cutoff at 1.5 kHz it gives the improvement a cool 15.2 dB, i.e. 6 dB rather than 3 dB. This would indicate that the noise is not evely distributed.

Some recieviers that I've seen does have a peak at 1kHz and a slow roll-off rather than a flat response with sharp cut-off at max mod freq. Can anyone try to explain why?

BTW I understand that pre/deemphasis is not a major player when looking at nbFM.

What I have to accept(?) is that the FM improvement is not due to the FM/AM conversion as such but the post detection bandwith limiting.
Or...???

The sucker should remove most of the mess, and the wick is used for cleanup. When using the wick, make sure and use a _short_ length (approx 1 inch), as the heat travels up the braid rather than into the work. I have had good luck holding the braid with needle-nose pliers.

Good luck,

I'm not quite sure what Mark is doing.

Sidebands are only produced when amplitude or frequency is being
changed.

Sidebands are not produced from a steady signal either on or off.

Since the receiver does not respond to dc, or store the signal, and
since energy (sidebands) from the rise and fall are gone before the
next rise and fall comes along, bandwidth does not change.

I think the problem is people are looking at the frequency domain when
it is a time-domain problem...and that has them totally confused and
frustrated.

That is fine, but the bandwidth of a traditional transmitter is NOT
set by the speed. It is set by the rise and fall times which LIMIT the
speed.

The signal requires a certain bandwidth to produce the rise and fall
of the enveloipe, and that rise and fall period sets the maximum
speed. If you slow the speed down with the same rise and fall shape
and time, the sidebands (clicks) extend the same distance from the
carrier.

Speed only changes bandwidth when the off and on time periods are near
the same length as the rise and fall times. That makes sense, because
it affects the rise and fall times, which is the only time when
sidebands are being generated.

Tom, your simpleminded and incorrect pseudo-scientific theory have been repudiated, time and time again. Even the self-serving and biased mathematical analysis that you have had others do (because you are incapable of understanding, let alone doing, the math), proves you wrong.

Why do you persist in embarassing yourself so by repeatedly posting demonstrably incorrect information? You've made claims that the ARRL Handbook is incorrect, and have failed miserably in making your point. When presented with factual information proving you wrong, you have attempted to redefine well understood terms to your own purposes. You have demonstrated a supreme ignorance of fundamental physics and mathematics.

You don't have a clue what "bandwidth" is, and since it has been clearly explained here a number of times, it's obvious you never will. What you're talking about is key clicks, aka spurious emissions. Yes, each key click has equal energy. No, they do not have any appreciable effect on bandwidth, and measuring how far away from the carrier you can hear spurious emissions has absolutely nothing to do with the bandwidth of a signal.

If my newsreader had filters, I would more easily be able to file your posts where they belong, the bit bucket. I am, however, concerned that there are people in this forum who are interested in learning about radio on a factual basis, so your bullshit should not go uncorrected.

I haven't tried a Samsung laser printer. It works fine on my
OKI LED printer and on my old Apple LaserWriter.

You can buy special film for the job. I had some success with
TEC-200 film. I have found that Epson glossy photo paper for
inkjets works even better. The advantage with the photo paper is
that it is water soluble. If you put the PCB in warm water, the
paper dissolves and floats away, the toner is left on the PCB.

Have a look at:
http://homepage.eircom.net/~ei9gq/pcb.html
for details.

Of all the desoldering techniques available, that one is my most hated.
Even when one finally gets the one procedure that works (squeeze bulb
with thumb; using your other hand wiggles the iron), the bulb expands
slowly enough that it never seems to get enough solder off.

Count me in the braid vs. solder-sucker religious wars as a follower of
the latter.

6112. New L-Match Design Program

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-03 18:29:05 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9pfml9qed3@neptunium.btinternet.com>
Source record: 49607

IMPEDANCE MATCHING WITH L-NETWORKS

The simple L&C L-network is capable of matching any pair of complex impedances to each other and, when used in RF power applications, it always has a lower internal loss than any equivalent T or Pi network using the same quality components.

Its disadvantages are that to cover a full range of impedances it is necessary to switch the circuit locations of L & C and/or change the direction of transmission. This means neither component can have a permanent ground connection.

Also, at the lower radio frequencies inconveniently large values of capacitance are sometimes needed. (T and Pi networks are popular because they can be designed to avoid these two disadvantages.)

But as the L-network has only two components and circuit changes can be quickly accomplished using alligator clips, it lends itself to simple homebrewing, wind-your-own coils, etc.

A new program L_TUNER is now available from website below.

For a given terminating impedance R+jX and frequency, and the required network input impedance (which may also be complex), L_TUNER computes component L & C values and offers a choice of network configuration.

Input to the program, R+jX, can be obtained sufficiently accurately with a modern hand-held antenna analyser. The program will be useful designing networks to match coaxial lines to the peculiar impedances found at the base of vertical antennas. Use program SOLNOID2 to design coils.

L-networks are used in other places such as amplifier outputs and interstage couplings. They tend to have wider bandwidths than other types of Z-match circuits.

Download program L_TUNER in a few seconds. One self-contained file of 39 Kilobytes. Simplicity itself to use.

I used to be strictly an assembler jock. I wanted maximum speed and smallest code size and maximum control over the code. Then I started writing C code out of necessity, and liked the speed; I rewrote some C stuff in assembler and found that in most cases the speed difference was negligible if at all noticeable, and realized that I could write the really time-critical code and/or code that the compiler didn't do well in assembler anyway and let the linkage editor do all the work.

Size isn't bad with C, either, with most compilers. There was a day long ago when only assembler could squeeze much code into the available memory, but the days are gone when we were forced into 1K of memory because they just didn't make anything bigger or let us interface external memory.

I can still beat the pants off C applications using assembler. But the difference is often empirical, and usually only exists in my own mind.

Hi.

Can someone help me with a link how to build vhf preamp?
easy to do but should work good.

Thanks.

============================

Shannon tells us nothing of the kind. It is essential to state
exactly what one means.

The amount of information in a message is proportional to the
Bandwidth it occupied when it was sent times the TIME it took to
send it.

To send the SAME messaage in HALF the time, ie., at twice the data
rate, requires DOUBLE the bandwidth.

Or, if you like, it will require TWO IDENTICAL CHANNELS alongside
each other. One channel transmitting the first half of the original
message and the other channel simulataneously transmitting what was
the second half of the original message, both channels operating at
their original data rate.

Its all sooooooooo obvious. The old telegraph operators could have
told you that as early as around 1830.

too often circuits are misunderstood by the newcomers who redraw circuit diagrams for publications like radcom, crossing lines are connected, some are missed and several other faults a trained and experienced person wouldn't do, even worse is QST, so my opinion is that those who draw the circuit diagrams are ofter newcomers

You are correct. Shannon states: C = B * log2(1 + SNR).

I did not fully qualify my statement, but it should have been quite clear from the context of the discussion. To make you happy, I will
restate: The more information you send in a given time, the more bandwidth you need (with a given s/n). My point remains unaffected.

Happy now?

It folded into Mechanix Illustrated, which was published by
the same company. I think the last issue was the Nov-Dec 1972
issue (I say I think because I"m sure I've said before it
was the end of 1971, and have since noticed there were 1972 issues).

I can't remember if there was an advanced notice, but in the final
issue there was an editorial telling of the combining of the
two magazines, giving reason for the benefits of the merger, etc.
The first issue of Mechanix Illustrated after that had "including
Electronics Illustrated" fairly prominently on the cover. I think
they had a fairly small section for the electronic content in
that first issue, though I long ago discarded it. I wasn't a subscriber,
but I did buy an issue or two after the merger, for curiosity sake.
I can't remember if that continued the next month or for a few
more months, but it didn't take very long before any reference
to Electronics Illustrated was missing from the magazine. Before
long, Mechanix Illustrated was identical to what it was before.

I think there were better hobby electronic magazines than Electronics
Illustrated. But it was the first such magazine I bought, the Jan/Feb
1971 issue; before I saw it that day in January 30 years ago,
I didn't know that there were such things as magazines about
hobby electronics. One good thing about the magazines of that
era was that they covered a lot of territory, such as audio,
ham radio, etc. And there was things to read in those magazines
about these sub-hobbies that were not of a technical nature.
So even though I knew nothing about electronics at the time,
I was only 11, there was still material that I could comprehend
while I kept trying to understand the technical material. If
it had only been a technical magazine, I wonder if I would have

kept spending the money each month.

As the hobby electronic magazines have slowly faded away, we've lost not only interesting magazines to read, but that cluster effect. Where do people read about ham radio now, except in ham radio magazines? I had already planned to get a ham license by the time I'd started buying the hobby magazines (I don't remember where or exactly when I first heard of ham radio, but it was in some general source, and had enough information to get me hooked) and started reading QST just a few months later, but as ham radio has disappeared from the hobby electronic magazines, where is the means to hook "fellow travellers" into our specific hobby?

These days, I think that is largely illusory, at least the size/speed thing. The top end C compilers are better than all but the best assembly coders. I doubt the low cost or free compilers are among the best, but C does tend to compile to pretty tight code, so I doubt it's very bad.

The control is another issue, however. I find a lot of the time I'm counting cycles with the PIC, either making multiple code paths the same length, or knowing the length of a code path. This would be horribly painful in C.

> but the days are gone when we were forced into 1K
> of memory because they just didn't make anything
> bigger or let us interface external memory.

Well, that's not exactly true, either. The most popular PIC for the hobbyist, the 16F84, has 1K of program memory, 56 bytes of RAM. And there are no memory bus pins brought out. If you want to interface to external memory it's serial memory. For some things not so bad, but for others, a real pain.

This may sound pretty horrible, but for the sorts of applications you apply it to, it's really not so bad. There are other parts with more memory, but the 16F84 is so often sufficient, that it's a pretty unusual hobbyist who uses one of the fatter chips.

Some of that I am sure is just inertia. I think most of us built our programmers, and while it wouldn't be hard to change it over for a part with more pins, it would be a pain. And I think we keep F84's in the parts drawer so they are there when we get the urge. It would be a pain to have to order something else. The something else's aren't all that expensive. DigiKey lists the F84A/20 for like $6. The 16F876, with 8K of program memory, 368 bytes of RAM, 5 channel A/D is still under $9. But most of the time the F84 is overkill.

Not so in the commercial world. The 'F' parts might be used for prototyping, but in the release version, one of the 'C' parts generally gets used, and nine times out of ten, it's one with less memory than the F84!

In an earlier post I mentioned the 16F627 and 628. I just started
using them and it gets my vote for the jellybean PIC to use instead
of the 16F84. The 16F627 is $3.20 from digikey (last I looked) and
its big advantage is you can use it at 4 MHz without any external
resonator at all (no crystal, RC, or ceramic). I think any 16F84
project should run on the 16F627. Any of the 8xx chips would be good
to keep around if you do bigger projects or need the extra features
sometimes.

And I agree that this is a place where assembler might make lots of
sense. I'd still try to use C in most cases if there weren't any
critical size or timing issues.

no.spam.lasse.moell@no.spam.swipnet.se (Lasse SM5GLC) wrote:

>Here is the tricky part, what is the distribution of the demodulated
>noise?

The noise _voltage_ after the demodulator increases in a linear way with increasing audio frequency. Thus, some people talk about the noise triangle.

However, it makes more sense to talk about noise (power) densities, which increases in a parabolic way with audio frequency. This growth will continue well past the audio passband and up to the half IF bandwidth, at which point, the growth will level off and the noise density will reach the peak soon after that and finally drop due to the slope of the IF filter.

By the way, it is this noise peak just above IFBW/2 that is used to control the ultrasonic squelch in some receivers. With a typical 16 kHz IFBW for 25kHz channel spacing, the ultrasonic filter should be set to peak at 8 kHz in order to filter out any audio signals below 4 kHz.

For a given carrier voltage, the baseband noise density is directly proportional to the IF noise density.

On the other hand, increasing the modulation index and hence IF bandwidth will only move the IFBW/2 point into higher ultrasonic frequencies, thus the peak of the ultrasonic noise density becomes higher when it moves up into higher frequencies.

With some reasonable modulation index (with an IF bandwidth at least a few times the baseband bandwidth), the audio passband will be in the beginning of the parabolic curve starting from zero.

Since the IF noise _density_ remains constant regardless of IF bandwidth, only the shape and height of the baseband noise density varies with IF bandwidth, but the size and shape of the noise density in the audio passband remains constant with constant signal voltage and constant IF noise density.

Thus, there will be a noise density increase proportional to the square of the audio frequency (+6 dB/octave) within the audio passband regardless of IF bandwidth for Carrier-to-Noise ratios >> 1. Integrating that noise over the audio filter bandwidth to get the total noise power shows that this is proportional to the third power of the filter bandwidth (+9 dB/octave).

>BTW I understand that pre/deemphasis is not a major player when
>looking at nbFM.

This is because the corner frequency is usually above 3 kHz, but since voice grade systems are usually limited to 3 kHz, there is not much it could do :-). However, phase modulation systems apply the "pre/deempasis" starting from the lowest frequencies.

For broadcast quality signals with - 6dB/octave deemphasis above about 3 kHz, will nicely compensate for that +6 dB/octave increase in noise density, thus, the total noise power is essentially directly proportional to the audio bandwidth.

For calling others names, you sure don't seem to grasp what sets
bandwidth of an actualy CW transmitter.

A carrier generates sidebands only when changing amplitude or
frequency.

6130. CW Bandwidth - Fullerphone

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-04 11:59:37 UTC
From: "owen.home" <owen.home@ntlworld.com>
Message-ID: <SeYu7.1076$jE3.269315@news6-win.server.ntlworld.com>
Source record: 49628

I haven't fully followed the CW bandwidth discussion but I'm wondering if anyone can estimate the bandwidth used in a Fullerphone - it's a DC signalling system devised in 1915 to prevent eavesdropping on land lines by the then Capt. A.C. Fuller, the rise and fall times were deliberately slow to eliminate key clicks and the system used buzzer/choppers at each end to generate a tone from the DC signal. The system was used extensively in WW2 and was even tested on submarine cables up to a distance of 700 miles with no other sending/receiving equipment although 20 wpm was the maximum rate achieved which I think points to a very low bandwidth and an extreme sensittivity for an entirely passive device -are there earlier DC chopping detectors?
I have a Mk4 Fullerphone although it's missing it's morse key, I'll try to measure the rise/fall times, a reference and circuit can be found at
http://home.hccnet.nl/l.meulstee/fullerphone/fullerphone.html
and original manuals at
http://www.qsl.net/n7cfo/fuller/fuller.htm

I hope this is relevant to the previous discussion and not too far off topic
Thanks

John

Tom W8JI wrote:

> A carrier generates sidebands only when changing amplitude or
> frequency.

It isn't exactly that simple. The spectrum of a pulse is determined by 1) the shape of the edges and 2) by the duration (width) of the
pulse. A 1 microsecond pulse with a certain *percentage, say 10%*, rise/fall time has a much wider spectrum than a 1 millesecond pulse with
the same *percentage, say 10%* rise/fall time.

For CW transmission, a string of short, fast dots with a certain percentage rise/fall time has a wider bandwidth than a string of long, slow
dots with the same percentage rise/fall time.

What we have been saying is that for a *fixed value* of rise/fall time, say 5 milliseconds, the bandwidth for a very slow code rate is
determined mostly by the rise/fall time, and that as the code speed increases the bandwidth of the code comes closer to the bandwidth that
is created by the rise/fall time.

I'll give you this, Tom, you are very consistent in your ability to be wrong.

A carrier modulated by a "square" wave of 50 ms on/50 ms off will have quite different sidebands than one modulated with 20 ms on / 80 ms off, even though both have the same amplitude changes and frequency.

If you are "salvaging" chips off a surplus board (to be discarded), the old favorite is using a propane torch.
I know it sounds dreadful and drastic, but you have to try it to believe it! Of course, the pc board will be useless after the exercise, but the chips will come out clean.

Just grab the chip package at the two ends where there are no pins. Most people use expanding pliers (like "Channel-Locks", etc.) to get a good grip. Then use the torch against the pins on the bottom side of the board. By gently wiggling the chip (with the pliers) you can detect when the solder on all the pins has melted sufficiently to free the chip, and you can pluck it out. I have salvaged scores of chips sucessfully by this method.

DON'T use this method for repairing anything where you need to preserve the pc board! This method pretty much toasts the board and makes it useless for further life as an electronic component!

See, my mom always thought I was just hoarding old electronic junk, but now it is called "recycling" and is politically correct!

Exactly.

The rise and fall time and shape of the rise and fall time determine
the bandwidth in a normal practical CW system used every day.

Speed has nothing to do with it, until the off and on times start
affecting the shape.

Sorry if these items are a little off topic, but I know that a lot of guys into ham radio and electronics may also have an interest in these kind of items:

I have for auction on ebay a B&K TV Tester, that is currently at $1:

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1013677222

I also have for auction a TV Rejuvenator that can brighten dim picture tubes:

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1013679879

For more pictures and info on these items, you can also take a look at my personal web-page:

http://i8mtm2.tripod.com/richardsjunk

Thanks for looking!

I don't think that will be too easy.

An analog Cellular telephone is a full duplex device and is highly
dependent on having the proper command and control channel, which
would be hard to duplicate. You would have to reprogram or replace
the internal microcomputer, which is probably a ROM based device (Not
reprogrammable). And unless your first name is 'Verizon', or
'Cellular One', you are going to have a hard time getting any info out
of the manufacturer on how the thing works anyway.

They are also 'wideband' FM devices and would not be compatable with
existing amateur repeaters or other rigs.

The best thing would be to tear it apart and see what useful parts are
inside. The QEX article mentioned in another post talks about using
cell-phone type parts for amateur use on 900 MHz, not on how to
convert a cell phone.

Me? I'm using my old Motorola MicroTAC to prop up my track ball at a
more suitable angle (aleviates carpal tunnel syndrome).

Also, look at the preamp(s) from Hamtronics:

http://www.hamtronics.com/lny.htm

I put one of these in an olde 2M Mirage amplifier -- replacing the
U-310 preamp that was there. Recommended.

Hello all,

I don't happen to have my license (sometime I hope), but I'm looking to make something which I've wanted to do now for quite some time. I finally have the means (money and time), now I need the what and how.

Basically I'm looking at replacing the security brain in my car. It's a 1990 300ZXTT. Replacing the brain is not that hard, chances are that a module from Z-World Inc. will do the job just dandy fine, along with a bunch of Ungo/Misc sensors to help augment things.

The problem comes along when I'm looking for a secure RF transmitter and receiver solution. The receiver could be on the bulky side, about 6"x8" will be fine. Lots to choose from, and since I have a brain on that side of the equation, almost anything is possible. The TX is another matter. I can't seem to find a module that is both small enough and does some form of random/encryption method to ensure that using a simple grad/replay method will not work.

Basically, what I need is a nice component, low-power, small part, that would idealy transmitt between 2-6 different key presses (on-off). Size roughly 1" square (prefer rectangular, but I'll take what I can get). I've tried to have a look at one of the Ungo TX (commercial), but there is too little there for me to figure out how it works...

Anyhow, if anybody has any pointers, I'd be very gratefull...

Source record: 49642

It will depend on what the preamp is hooked to. Look at the noise
figure of the preamp. It is rated around 4 db. If the preamp is to be
used with a sensitive receiver then the noise figure is way too high. It
should be under 1 db. With modern devices it is possiable to get to
under 1 db of noise figure and have about 15 to 20 db of gain over a vhf
and above ham band.

I am not sure what device the preamp uses but you can get some of the
MAR series devices from Mini Circuits that have about the same gain and
noise figure. All it takes is a resistor and a capacitor on the input
and output and a couple of capacitors on the power line to do the same.

6146. NY/NJ/PA "Radio" Octoberfest this Saturday

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-05 01:53:16 UTC
From: k3bu@aol.com
Message-ID: <20011004215316.08376.00001073@mb-ch.aol.com>
Source record: 49643

Reminder.
NY/NJ/PA "Radio" Octoberfest this Saturday

You are all invited to (Radio) Octoberfest at Verkhovyna Mountainview Resort in Glen Spey, NY (NY,NJ,PA tri-state area) hosted by the Tesla Radioclub and Ukrainian-American Cultural Foundation - UACF on October 6, 2001, starting at noon till ???

Come and have fun meeting other hams, DXers, contesters, while having good time and drinking Octoberfest beer. Enjoy Ukrainian and German food, listen or dance to endless polka's. Wear your badge, hat or shirt with callsign proud and meet other radio aficionados around the "radio" table.

140 acre Verkhovyna resort is the new home to Tesla Radioclub N2EE station. Join the semi-serious discussion of how many towers do we need to put up there. Come, join the club and get a free beer.

Directions:
Take Hwy. 84 to Port Jervis, NY exit 1; follow Rt. 6 through Port Jervis to traffic light with Rt. 97/42 signs, go through and follow Rt. 97 west for 10.8 miles to Pond Eddy (motel on right, bridge on left), turn right onto High Rd. (Rt. 41), go up the steep hill for 1.7 miles, Verkhovyna is on the left. Plenty of parking.
Maps and sattellite view of the resort are at www.UACF.net home page under directions.

See you all there and join us yodeling in Morse code :-)
Nazdorovya, Ein Prosit!

Yuri, K3BU
pres. Tesla Radioclub

Paul
thanks for clarifying these issues for me!! I guess I'll bring a print-out and six-pack into the sauna tonight and try to fully grasp the subject! BTW I found a good book (in swedish thou) dealing with signal theory and it tries to explain the process without using excessive theory ;-)).

There is one more thing that be puzzes me, the limiter. How much improvement does it really give? Some claims that the limiter is essential and can give up to 6-7 dB, whilst others say it is merely acting as a fast AGC and in an gaussian noise environment only contributes to less than 1 dB improvement. I guess it is dependant to what C/N is used. Some improvement is likely to appear _if_ operated under the "dector knee" but how much?

Suggestions and comments are most welcome

I have not looked very closely at this, but it is quite common to
think about a carrier into which white noise is added with a random
phase. The noise is divided into two components, the one that is in
phase with the carrier (I) and the other noise component which is in
quadrature with the carrier (Q). The limiter will remove the I
component and only the Q component contributes to the audio noise, so
intuitively I guess the improvement should be 3 dB, but since the
limiter is working only during a part of the carrier cycle (not active
during zero crossing), the improvement should be less.

You are problably correct, but in theory shouldn't the FM demodulator
be insensitive to AM, which is removed by the limiter?? The limiter
should not do anything about the FM noise or? (i.e. in theory...)

It's getting interesting when the c/n is below the knee and acts
highly unlinear.

I thought of that, too, Joe. It would keep the car from moving when
operating stationary mobile.

How about tying a rope around an old cell phone and using it to get
the end of your dipole over a tree limb?

On a more serious note....

Some of the __Realy___ old first generation cell phones (bag phones
and in-car, not to mention base station channel units) have a more
open architecture and __could__ possibly be converted. I have seen
some base units that had 8085 micros, and all the RF stuff is out in
the open. Used to have a complete manual on the things (GE, if I
remember) in my previous incarnation as a cellular RF engineer. No,
don't ask...I don't have it anymore, but I have seen the units offered
in magazine ads.

Sounds like a good Christian radio show. What channel do they carry it
on?

All joking aside, those old analog bag phones might still work if you keep the battery charged and can always be used for 911 calls whether activated or not. I keep one in our motorhome for emergency use in the boonies when out of cell range if we ever have problems.

As I recall from my Advanced Modulation Theory grad course at MIT back in the 50's, the limiter operation together with post-limiting filtering is at the heart of the merits of FM operation. I long ago disposed of all my class notes from those days and we used no text, so nothing I can show you.

But, I can refer you to the excellent treatise on modulation theory written by my professor for that course, Dr. Elie Baghdady. He did his doctoral dissertation on FM system analysis and innovations and at that time was probably the world's leading expert on modulation theory, especially FM.

Elie used to say smilingly that "the" secret was to limit the signal severely to spread it and the noise and interfering signals over a wide frequency range and then post-limiter-filter to regain the desired signal, now greatly improved in S/N.

"AM noise" or the in phase component is removed by the limiter.

>The limiter
>should not do anything about the FM noise or? (i.e. in theory...)

The quadrature component of the noise will frequency modulate the
carrier with some modulation index, producing audio noise.

>It's getting interesting when the c/n is below the knee and acts
>highly unlinear.

Well below the threshold, the detector is captured by the noise (not
the signal), so the situation is not that complex, however, when the
signal level is transiting from the captured by noise situation to the
captured by signal situation, this is quite complex to predict,
especially if the signal strength is constantly transiting through
this area e.g. due to mobile flutter.

http://www.halturnershow.com I think they call it "balance".
My recollections are of one black acquaintance of mine who had
a saying; "There's only two kinds of women in the world:
Whores and Bitches... There ain't no other kind."

Never mind that all the hookers in town gave their money to
people just like him so they could keep themselves in hi-heels,
and Heroin.

Reminds me of another saying; "Take my wife... PLEASE!"

If it were OK to kill the messenger, all reporters would be dead.

6160. L.O.S.A - List of Stamp Applications [011005]

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-05 16:11:22 UTC
From: cjX@hth.com
Message-ID: <3bbdc9e5.59918444@news.sverige.net>
Source record: 49557
Cross-posted to: comp.robotics.misc,comp.home.automation,sci.electronics.misc,rec.radio.amateur.homebrew

Hi,

Below is the latest index of L.O.S.A and it now contains 230+
BASIC Stamp projects. You can download the complete L.O.S.A
from the following places...

WWW:

http://www.hth.com/losa/

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 What is L.O.S.A all about?

This list was started back in -95 when I heard about (more or less)
uniqe problems that was solved by using a BASIC Stamp. Especially Guy
Gustavson's story (see #001) about how he saved his beloved cat Kesha
gave me the inspiration to start writing L.O.S.A. I hope Kesha still
is alive and having a great life. Now 6 years later there are 230+
applications described and I hope you will enjoy reading all (or
parts) of them.

The main purpose of this list is to get an idea of what other people
are using their BASIC Stamps for and maybe get some inspiration or
hints for your own projects. Some of the projects described in the
list also have links to source code and schematics for download.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa/

1.2 Why are some links dud's ?

Since people changes their e-mail and web addresses some links may be
dud's. If you previously contributed with one (or more) of the

applications please take a quick look and check your e-mail address
and/or web-links. I'm only able to keep the list updated if I'm
informed about changes, thanks in advance.

1.3 List of contributions

> boot? Is this recomended..

You can, more or less . . . The 4CX350 is a bit different inside, and is only for class AB1 linear operation. The grid can't handle any grid current, like a 4CX1000.

Power output remains the same as before, as the plate voltage and current will remain the same. All you get is increased plate dissapation, which you really don't need.

> Will it be best to just buy an 8 ohm speaker and put it in the cabinet?
> Thanks for any help. Bob

Best answer is to use an 8 ohm speaker. Using a resistor will work, but
half your audio power gets turned into heat. Now if the output stage
doesn't have a transformer, which most circuitry doesn't, you can use
the 4 ohm speaker, but don't crank the audio way up. This might make
the audio output transistors or IC go pooof.

audio speaker impedance is a nominal figure; in reality it varies widely
depending on what frequency you put into it. a good hi-fi 8 ohm speaker
may vary anywhere from 3 to 50 ohms, at certain frequencies.

Boy that goes back a few days . . .

I remember that TU540W is wide band (40 kHz) and TU540S is narrow (16 kHz). These are common in the Sensicon G receivers. They are driven by 1/2 a 12AT7, and then feed a 6BH6 or 6CB6. I would presume that they are hi-Z in and out. The rest of the data, your guess is as good as mine. You might try to find a book on the T4xG or GGV series radios, and study the schematic. Or if you can find one, a FM Schematic Digest; it has a synopsis of most of the early tube Motorola gear.

What's inside is mot much more than LC circuits tuned for a passband characteristic, and cast in styrene plastic to maintain stability.

If you see a smallish one that looks like three cans sticking out of a small box that is a Tri-K filter, and it is really broad. Some of the older Sensicon A receivers may havae a wide band filter, as many of them were not changed over due to cost. If you see a ink stamped part number and it has an "S" that usually indicates narrowband.

FYI, Stanford Microdevices has some pretty neat parts. There is one
unit in the line that (AFAIR) provides about 1.9dB NF around 1GHz, and
maintains good perf well above 2-3GHz, and is able to provide around
50mw power output. All perf measures are made at 50ohms I/O.
I think that the part number is the SGA-4586. Price is in the $1-$4/ea range.

Except for the lowest noise app (e.g. pointing a narrow beam antenna at the
sky, or eeeking out the abs max perf), there are some really nice gainblocks
nowadays at reasonable prices. I heard a rumor that Stanford Microdevices
is the source for some of the Minicircuits parts.

Avnet has recently made available an experimenters kit for the Stanford Microdevices
parts are a really favorable cost (about $80???) Richardson Electronics? also
seems to be friendly when purchasing small quantities of the parts (I usually
purchase in the qty 10 or qty 20 range.)

I'd just get a CB radio and modify it. I'd reccomend a HyGain V SSB unit, as it takes one crystal changed to put it anywhere. It should tune into 10 without any problems. Stay clear of the old 23 channel crystal rigs as you'd have to build a vfo of some sort.

Now 12 or 15 meters is a problem, as you'd have to add turns to coils, etc.

Or, if you want to spend some money, pick up a Radio Shack rig, or a RCI or Ranger. Occasionally you might see one at a pawn shop, but they don't go cheap.

Hi Mates

found a small box of these chips, wonder what they are. perhaps a cache or video memory. it's in a 40 pin so dip lcc. Logo on is a circle with a group (square) of 9 dots in the 9-12 o clock quadrant. They have a 99 date code so they must be for fairly recent designs. Any help would be appreciated.

Well, I used to work at SBE so I had access to scrap CB's and all of the schematics. Taking one to 15 meters wasn't too tricky. I placed capacitors across the tuned circuits and it was 'close enough'.

Admitted, the synthesizer was more complicated.

Taking one to 40 meters, now THAT was a challenge. Did it, but would not recommend anyone try to do that one.

==========

Overall, I think converting a CB to 10 meters is fairly simple, anything else would be more trouble then it is worth due to the channelized operation and how hard it is to retune everything.

There are a number of very good kits that would probably be a better way to go. Perhaps a bit more expensive then a scrap CB radio, but better overall performance.

>Well, I'll admit I'm on the gullible side, myself.
>At one time I thought internet stocks were a
>pretty good deal.

Heard on the radio a couple weeks ago:

If you bought $1000 of Nortel stock a year ago and sold it today, you'd
get $49.

If you bought $1000 of beer a year ago, and drank all the beer, you'd
still get $79 when you returned the empties today.

So beer was a better investment than Nortel - even if your ignore the beer.

Hi, radio folks!

This is JF1VHX from Kawasaki, Japan.
I'm afraid the MF Richard mentions is not labeled "MF-455-|OCK."
It's "MF-455-10OCK" which is a can-type MF.
I know nothing about this MF except it's an older model
than MF-455-10AZ which is a box-type MF.
YAESU's FL/R-400 and FL/R-100 series and Trio's JR-310 use MF-455-10AZ's.
I and many Japanese friends of mine successfully restored this MF.
The original restoring method comes from JH1NUK (Mr. Toda)
and I just followed his method.
As Sverre said, I added to my site a sub-page about
the restoring process.
To browse it directly, just click the address below:

http://home.catv.ne.jp/dd/te21c/mf.htm

I know a certain Japanese OM is going to restore MF-455-10OCK.
I will let you know when he has succeeded.

Good luck, JF1VHX.

>

Yep, George, I have a couple of them stashed in the trunks of vehicles
for 911 use. Seems the activated pocket phone is often "elsewhere".
Even if the old batteries are not charged, the cigar lighter plug will
make it work, mine have the capability to unplug the battery and just
use the cigar lighter plug just be sure you have an antenna available.
And I understand they run 3 to 5 watts instead of a couple hundred
Miliwatts as the handhelds do. That, with a magmount antenna to stick on
the roof if needed should give considerable better range in fringe
areas.

I guess everybody knows by now that the FCC mandates cell carriers to
allow free 911 calls, even on phones that do not have an active account.

Anyone got any suggestions preferably on something they have had a go at building themselves, on a CW Transmitter. I am looking to build something cheap as my first project, but I am aware of the need for Low Pass filters and so I want to find out as much about them as possible too. There seems to be alot of CW transmitters available over the web, but very little info about Low Pass filters.

I passed my Ham Exam December 1999, and never quite got round to sending off for my licence here in the UK as the expense of the sets were a little off-putting (according to my wife). Now I intend to learn morse an make a QRP transmitter for the 40M band.

Thanks in advance, all comments (even flames) welcome.

for a hundred or so bucks (american), you can get a decent new or used cw rig
from MFJ Enterprizes.
You can build one for about 10$ from a crystal, coil, capacitor and transistor.
It puts out a watt or so. Search the web for the Michigan Mighty Mite, or the
Peanut Whistle.

80M is a good place to start. Most good junk boxes have a 3.579MHz crystal
in them. Even if you have to buy one, it won't cost more than a
quid/euro/dollar...

A CB PA transistor will work very well in the output stage.

You will find details about my simple CW transmitter at:
http://homepage.eircom.net/~ei9gq/tx.html
Low pass filter included.

6183. Any one have experience with the AN762 Amp

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-06 20:59:40 UTC
From: Jobst <jvandrey@geocities.com>
Message-ID: <0hKv7.8059$2p1.813971@newsread2.prod.itd.earthlink.net>
Source record: 49581

I'm looking to build the Linear Amp described in the AN762 note by Motorola using the component set available from Communicatrion Concepts.

Anyone have experience with this device?

I'll be using it with a Elecraft K2 in digital modes (Pactor II and PSK31). Elecraft will be running at 2 to 5 watts out. My intention is to use individual low pass filters mounted in shielded boxes with SO239 series connectors for the bands of interest instead of trying to build a fancy band switch system. I only use 20, 30, and 40 meters so this should not be a big inconvenience.

Thanks in advance for any information.

Jobst

There were some of these filters used in Motrac and Mocom 70 rigs. I took one of these things apart, and found 12 455KHz ceramic filters, with a transistor stage embedded in them.

Hello,

I'd appreciate some recomendations for circuits of simple digital displays. Ideally I'd like to build it from scratch (perhaps purchase the PCB and programed PIC chip) but failing that I'll consider a kit too. I have some fairly specific requirements though to fit my rig.

1. Must be LCD in order to save power
2. Low supply current
3. The smaller the PCB the better

The only kit I'm aware of that fits my needs is by AADE in the US and this takes I believe about 15 mA on a pretty small board, but as I said I'd actually prefer to build (almost) from scrath. I've looked through all books and mags and come up with very little. Any Ideas for Circuits or kits?

73,
Mike, M0BST

Latest versions of the Car and Deep Cycle Battery Frequently Asked Questions (FAQ) maybe found at www.uuhome.de/william.darden The Car Battery FAQ contains non-commercial, consumer information such as buying a new battery and jump starting batteries found in cars, trunks, vans, motorcycles, boats, snowmobiles, jet skis, farm tractors, lawn and garden tractors, SUV's, etc. The Deep Cycle Battery FAQ contains information such as storing lead acid batteries used for most recreational and commercial deep cycle applications. Also, you will find a Battery Manufacturers and Brand Names List, Battery References and Information Links and printable version of the above.

Please bookmark the new web site. If you have any questions or comments, please email me at bjb_darden@yahoo.com

Best regards,

BiLL.......

How about audio?
http://www.extremezone.com/~nk7m/cwafc.htm

Saves the space of the display and you don't have to look at it to
get the readout.

There is another one called the Freq-Mite from;
http://www.smallwonderlabs.com/
But I think they are waiting on boards before any will be ready to ship.

Intriguing thread

A few years ago ,on a flea market , I bought a probably WW2 US Navy VHF transmitter with a x-tal oscillator (4 channels, 4 xtals in an oven, but no xtals fitted) ,utilising an 807 followed by 3 pcs 829B ,the first 2 each being a tripler . No manufacturer/model number shown.

The anode region of the last tripler and the PA are cooled by air from a centrifugal blower.
The rx/tx co-axial switch (with N-sockets) is operated by a solenoid type ,pinion/rack arrangement (clink-clonk).
The PA output circuit has 2pcs 3/8" OD round bars abt 4" long ,with shorting bar ,the latter with a midpoint anodes voltage feed via the usual RF choke (a few windings around what looks like a 1 Watt resistor)
PA tuning is done with a dual var. capacitor (insulated) with the stationary plates connected to the 2 anodes.
PA anode current meter has range 0 - 300 mA and the grid meter 0 - 20 mA.
It is possibly a TX for CW ,no modulator is part of the unit.

Does any (US Navy) Old Timer on this NG recognises this TX ?

TIA for any info.

Frank gm0csz.kn6wh@ntlworld.com

6192. Help measuring desense

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-07 20:55:31 UTC
From: Shawn Reeves <kleptein@hotmail.com>
Message-ID: <en01stcmrmnjt7lpa418p9leibgioucp3p@4ax.com>
Source record: 49588

I've recently tuned a new duplexer, and am trying to assess the amount of desense. I understand that I need an Iso-t, but am not completely clear on the construction, nor the procedure. Searching the group I was only able to find one very complicated description which didn't help very much.

My questions are, what is the procedure to measure desense in a repeater/duplexer setup, second, what amount of desense is acceptable, and third, how do I reduce it?? (Duplexer tuning?)

Thanks!

Shawn

6193. Has Frontier Cap closed

Hi,

I saw a note elsewhere on the net that Evert H has closed Frontier Capacitor. If this is true, who is selling metalized polyester tubular caps?

AES prices seem to be about twice the price of Frontier's.

Regards,

Bob

I agree with that. Unless you have a very specific need to match 50 ohms. I just put together a MAR-1 amp using 2 of the devices. I used a piece of unknown PC board and cut several small pieces about 1/8 inches by 1/4 inch. Glued these to the larger piece of PC board to make islands to mount the leads. Used some .002 mfd capacitors on the input and output and one for coupling the 2 stages together. Had about 30 to 35 db of gain from 30 mhz to 450 mhz.

I am not sure if you are the one I responded to or not. The iso-T can be built by taking a so239/pl259 T and removing the center pin. They usually remove by unscrewing them. Then screw a doubel female conector into it. This is the port you hook the signal generator to. Then if needed a short screw can be installed in its place, just be sure it is not long enough to contact the female connector. YOu just want a small ammount of capacitanc coupling. It should be about 30 db or more of isolation.

You can also install a seperate antenna where it will not move inrelationship to the repeater antenna and drive it with the signal generator.

It will take a lot of signal from the generator to get a signal on the receiver. Remember you are loosing about 30 db in the iso-T. You want just enough signal to hear, say the equivilent of about .5 microvolts at the receiver input. This is with the transmitter off. YOu then turn the transmitter on and see if the signal is degraded. If it is you increace the signal generator tuil you get the same sinad you had to start with. The desense is the differance in level with the generator off and on.

YOu should not be able to detect any desense on a very good system.

If you have any, then tune the duplexer, see if the transmitter is giving a clean signal, make sure the RF is not getting into the receiver except by the coax, use good double shielded coax. YOu may need to add more cavities to the duplexer.

6197. 5763 tubes for sale (cheap!)

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-08 03:01:32 UTC
From: mjsilva697@earthlink.net
Message-ID: <27085883.0110071901.7c2bf190@posting.google.com>
Source record: 49593
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

I am posting this for somebody I have had good dealings with. She has lots of 5763 tubes that she would like to sell for $25.00 per hundred (yes, 100). She wants to be able to park in her garage again <g>. These are late production (1985) Phillips / JAN.

For those who don't know the 5763, it's a 9-pin mini beam power tube, good for up to 175 MHz. Plate dissipation is 13.5W, maximum B+ is 350V*, max Ip is 50 mA, and gm is 7000. Unlike most beam tubes, the beam plates come out on a separate pin, so there won't be excess coupling to the output in circuits where the cathode is above RF ground. Overall I tend to think of the tube as a high-gain 6AQ5 with good RF credentials.

The 5763 was one of the ARRL recommended oscillator tubes, along with the 6AG7 and a few others. It was also used often as a driver tube, and as a PA tube for low-power and/or mobile rigs. One of the last ARRL "How to Become a Radio Amateur" tube transmitters was a 6C4-5763 rig. It has a fairly high gain/Cgp ratio, meaning one should take reasonable precautions in layout, and it may in some cases need to be neutralized. I don't see why it wouldn't also make a good audio tube akin to the 6AQ5 and 6V6.

* Given that the plate is on pin 1 and pin 2 is a N/C, I'd bet the tube could be run at up to 500V by removing the socket connector for pin 2 (to extend the leakage path). That would be 25W input for a 25 cent tube...

May I ask the obvious dumb question. Please?
Question: "Why is the foam in there in the first instance and what
function does/did it perform; if any?"
Terry.
PS. I have two older (circular Collins mechanical filters) frequency
currently unknown but AFIK they are either individual 'channel' or
perhaps 'channel group' filters from late 1950s vintage Collins
telecommunications multiplexing/carrier systems. Would THEY have 'foam'
in them?

6201. List of the rec.radio newsgroups

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-08 05:30:33 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <9prdlp$c8s$1@news.hawaii.edu>
Source record: 49497
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

```
Archive-name: radio/personal-brief-introduction

In an effort help ensure a poster's article reaches the appropriate
audience, below is a list of the rec.radio newsgroups. In most cases,
a group's name will explain its purpose. Cross-posting should rarely
be necessary.

rec.radio.broadcasting (devoted to the broadcast industry; moderated)
rec.radio.cb
rec.radio.info (periodic informational bulletins; moderated)
rec.radio.scanner
rec.radio.shortwave
rec.radio.swap (for buying, selling, and trading; not a discussion group)

rec.radio.amateur.antenna
rec.radio.amateur.boatanchors (tube-type communications equipment)
rec.radio.amateur.digital.misc (packet, pactor and other digital modes)
rec.radio.amateur.dx (long-distance amateur communications)
rec.radio.amateur.equipment (questions, comments regarding commercially-
built amateur gear; not for buying/selling)
rec.radio.amateur.homebrew (devoted to home-building ham gear)
rec.radio.amateur.policy (issues include code, restructuring, local
restrictions in conflict with FCC R&R)
rec.radio.amateur.space (satellites, meteor scatter, EME)
rec.radio.amateur.misc (any amateur topic not covered in the above groups)

(At least two other English language radio hierarchies exist, prefaced
with "uk" (United Kingdom), and "aus" (Australia), in place of "rec.")

Again, cross-posting should rarely be necessary. Many times, a long-
running thread results from a single cross-posted article, and its
content drifts further and further away from being "on-topic" in the
various NGs which receive each and every followup.

For more detailed information, see "Guide to the Rec.radio Newsgroups"
posted on the 15th of each month.

I have just taken delivery of 50 boards for this controller
On board there are interfaces for keypad, rotary encoder, LCD display,
serial port and programming interface
See http://www.iinet.net.au/~richardh/VK6BRO.htm

Source record: 49503

I built my first CW TX about 2 years ago. Since I already had the HV transformer I made a tube based TX. The final is a 1625 and I got 3 of them for $3 each. It cost me a grand total of about $20 - $30 to make it and it puts out about 50W on 80m and 40m. Works great. Anyway here is one of my favorite sites.

http://hem2.passagen.se/sm0vpo/

Harry has a lot of projects, hints and tips for those on a budget.

I did implement a broadband amp for HF distribution use (1 to 30 MHz) using paralleled pairs of MAV11s in push pull, matched to 50 Ohms with a 1:1 balun at each end, 4 total in the amp, to get maximum dynamic range. The amp has a gain of about 8dB from memory and very good IP3, > than 35 dBm at which point it gets hard to measure... No striplines, just built on unetched pcb material, which technique is fine up to about 220 MHz; above that you should consider using striplines. These can be cut directly on the board with an exacto knife for a small amp

Source record: 49506

Both the 2E26 and the 829 have been used as drivers and finals throughout the years. In the 50's and 60's... Motorola made many a commercial two way radio and repeater using said tubes in their "Research Line" of equipment. I still have some in storage. GE was also making similar equipment.

There is a very popular ARRL Handbook amplifier project using the 829... I've even seen a commercial unit made/sold by Gonset using the 829. I built the Handbook amplifier and still have it.

The 829 gave way to the similar style 5894 which still lives in the last of the tube repeaters in service. Lot's of watts with little work. Good onto the VHF Bands with no problem.

Thanks for the walk down memory lane Gary... It was funny that Motorola gave a lifetime warrenty on those filters but refused to honor it in the 80's We gave them a lot of grief over that... they just offered trade in deals instead.

cheers
skipp

Can someone point me in the direction for a reference part substitutions? Specifically, I'm trying to build a reciever which calls for a SK3835 germanium transistor or equivalent. I can't the asked for transistor and can't choose a substitute cuz I don't know what I'm looking for. It's a good day when you can find the resistor you want at RS and Mouser lists nothing that I'm looking for. Also, can someone tell me what transistor fits the description "hi-frequency, small signal"? I presume it might be the ubiquitous 2N2222 but I surely don't know. Building stuff is the easy part. Finding parts based on vague descriptions is such a pain I may just give up building.

Help please

Mouser p/n 599-SK3835, about $2.

Also, can someone tell

Insufficient information. PNP? NPN? max voltages? hFE?
2n3904 or 2n3906 might be appropriate.

The "SK" is a general replacement series by RCA. "NTE" is a replacement series by Sylvania (I think). Both have substitution books which cross many numbers to one of the replacements in their respective series. You can often find these books at an electronic wholesaler or perhaps on the company web pages.

14 Amateur Radio Clubs have organized the Lake Placid Hamfest on October 13th.

For all who live in Eastern New England, and Canada, a group of Northern New York Amateur Radio Clubs got together to have one hamfest. This will be in beautiful Lake Placid, home of the past winter Oylmpics.

This will be ideal to drive up or down with the YL, XYL, or your ham buddies. The fall colours will be in bloom.

NOTED: QRP'ER BRIAN RILEY N1BQ, WILL BE GIVING A QRP SESSION / TALK.

Wasn't EI the one with those little chess puzzles in it? I am
not a chess player (and never was) but I always did like to try
to solve those "white to move and mate in two" puzzles. I
always solved them, too before I saw answers in the next issue
of the magazine. But there was one that I could never solve;
guess which one! Yup, the one in the last issue.

I have often wondered if the editors put an unsolvable
puzzle in the last issue out of spite, knowing that there
would be no "next issue" with a solution!

Oh well, now I will never know. I have since lost my copy
of the last issue of the magazine (and the chess puzzle that
was in it).

Hi, Tobias.

The September 2001 issue of Electronics World (a hobby electronics magazine from the UK) has a most interesting article in it, "Code-hopping reomote control", pages 672 to 678 (EW is one of those magazines that begin on page 1 in the January issue and end at about page 1000 or so in the December issue).

Anyway, this article shows how to design a secure RF remote control system, using Microchip's Keeloq code hopping chips, and a wireless UHF Rx/Tx module pair by Radiometrix.

I bought my copy of EW at a local Chapters store for CDN$8.50, but they may be off the shelf by now.

You can get specs for Microchip's Keeloq products from http://www.microchip.com, and for the RF modules at http://www.radiometrix.co.uk. There may be North American suppliers for similar modules.

Hope this helps.

Regards,

Ed Pugh (VA3PU)
Ottawa, Ontario.

From: mike@corn2.freeserve.co.uk
Message-ID: <3bc412e5.4796282@news.freeserve.net>
Source record: 49526

HI Folks,
Has anyone experience of the FT-707 ?

My FT-707 has developed a problem, on SSB or CW recieve, the "S" meter indicates about 50% fsd and the reciever appears to be _very_ quiet but is recieving signals. On AM the reciever comes back to life and the "S" meter drops back to normal.
The transmit side appears to be fully functional with the meter indicating PO and ALC correctly.
Normally the "S" meter will deflect toward fsd as the RF gain is reduced. This still happens on all modes but is now partially 'hidden' by the fault on SSB and CW. Switching between fast and slow AGC has no noticable effect on the fault condition.

I suspect an AGC fault (unlikely only on ssb and cw ?), but any other ideas appreciated.
thanks Mike W, G8NXD qthr

Did you try to "isolate" the op-amp output and feedback resistor by
inserting a small series resistor driving the capacitive load (the
feedback resistor is directly connected to the output).

I built the kit from AADE and it works just fine for me. My application
was peculiar as it was being used in a tube radio with a 458kHz IF. I
highly recommend it.

Support from Neil was great -- I thought I nearly wore him out with my
questions and he still came through. Great guy.

I have a VHDL FPGA model for same, driving LED displays, forming a counter,
or a receiver frequency display. It is a proven design, but never been
synthesized. I bought the AADE board because I wanted to get on with it.
Someday I will synthesize my design.

Drop me a line if you want a picture....

I think this is a low noise quad op-amp. The dual op-amp version is the LM833. 4 nV/SqrtHz..... Very low noise. Mouser or Digikey will carry it. Another dual part is the LM5532. It has about the same very low noise specifications. I know Mouser has that, but it might have another suffix, like NM5532 from another manufacturer. These cost less than $0.50 for the dual parts.

I have a bunch of LM833s if you need a few.

Another thing; did you put a decoupling network in the supply lines.
Depending how much current you need to deliver, a 10 to 47 Ohm series
resistor in each supply line, with a 220uF cap in parallel with a .1uF high
frequency cap might do the trick. Also, the series R in the output circuit
that Paul suggested would be very good.

One thing that could cause the problem is if the BFO insertion frequency has drifted into the I.F. passband. If it were that, though, you would probably notice that the audio had a more "muffled" quality.

Gday Mike, I have an FT707 myself and a circuit diagram. A portion of the IF output is detected and amplified by a fet Q2020 and Q2021 then fed to the LED's. If your receiver is quiet the problem is probably in the agc circuit which controls the RF and IF amplifiers. The output from IF amplifier Q2005 is fed to a buffer Q2018 then to diodesD2024 & 2025. The resultant DC voltage is amplified by Q2019 and fed to the gates (2) of the RF and IF amplifiers.If you can identify the components on the board it would be worth checking the diodes and the transistors involved first. I think it unlikely to have shifted off frequency if the receiver stll works albeit quietly on SSB and CW mode. Hope that is of some help. Let me know if I can help further, Regards, Renfred ZL1BDL

it seems that AGC circuit is faulty or incorrectly adjusted, perhaps a
component is bad, so I would force the AGC voltage back to where it
should be for no sigal input and see what happens

FT-707 might be a later version than FT-7, and I never experienced any
AGC trouble with FT-7, while some older FT-101B seems to have a
constructional problem

Short news articles in "EI Picturescope":

NOW SHOWING--What looks like three drive-in movie screens and a domed refreshments stand, isn't. The screens, each one the size of a football field strung up by one side, are part of the antenna system in the detection radar of this BMEWS (Ballistic Missile Early Warning System) installation in Clear, Alaska. The dome, a 140-foot sphere, covers newly-installed RCA long-range tracking radar that can predict point of impact of any hostile missile impinging on its field, even if it is thousands of miles from the installation.

SEEING EYE--Less than one per cent of the light that comes from a full moon is all the Toshiba multistage image tube needs to produce a picture on its screen. The image in the small insert at the top was picked up on the tube using only the stray light from the panel meters and elsewhere in the equipment itself. Unlike infrared devices, the tube uses visible light focused on the photoelectric surface of a screen that delivers electrons to a series of TSE (transmission secondary emission) multiplying dynodes. Output electron stream is focused on fluorescent screen. TSE dynodes are extremely thin metallic membranes that, in effect, add electrons to electron stream as it passes through.

Source record: 49544

Greetings,

In a remarkable feat of stupidity, a small RF can-type slug-tuned transformer was forcibly separated from it's mounting point, and rendered useless. The XYL doesn't buy the argument that this is a sign from God that I should purchase a new FT-1000MP MkV or Omni VI+. Therefore, I need to repair my radio.

The device formerly resided in my FT-301. It is/was T701 on the PB-1439A premix unit. The parts are no longer available from Yaesu. I've posted "wanted" ads in other forums, but in case I have no luck, I'll need to find/make a substitute.

The transformer is marked "Mitsumi" on the top, with "220 017 6NG8" on one side. Mitsumi's web site doesn't list this part, or anything similar.

There are similar parts available from Toko and others. Empty shielded/can-type slug tuned forms are also available, so I can wind my own.

How can I determine the specs of the original part? Would an L meter help (I can probably borrow one)? I have the circuit diagram for the radio, is there any way to calculate what's needed?

TNX es 73,

I'd use dual couplers, toroids perhaps, one for the forward and the other for reverse.

I think the non-linearity of detector diodes would make them unsuited for this. They respond differently at different RF levels.

So, I'd use one of the log detector chips from Analog devices.

The AD8307 would serve... And by using these chips, the relative voltage difference between the two detectors would be a direct reading of the return loss in dB.

This would remain constant regardless of absolute RF level, and also regardless of what band you are on.

Yeah, the AD8307 isn't all that cheap, but the performance of the design would be solid and repeatable at pretty much any RF level. Here is a link to a website that has the IC and also the rest of the parts if you wanted to make an RF power meter.

Hi,

Some of this depends on what kind of amp you are talking about. No matter what you do a SSB amp will be significantly more difficult to protect than one running CW or FM.

What's often done is to simply sense a fixed level of reflected power. The logic is that the amp will not be damaged by high swr at low levels. All that takes is a simple directional coupler and a detector. The detector feeds a comparator and if it's an SSB amp a one shot.

Enjoy!

Terry replies ....

That's great information, thanks John.
Interesting that, as you say, the Collins filters don't seem to contain
foam.
The method of coupling between the elements then must be mechanical?
Not electromagnetic? For some strange reason, (mental block maybe!) I

Have less problem, visualizing resonance in a crystalline structure such as a piezo electric crystal!
Funny that I worked with equipment containing mechanical filters but never bothered to find out exactly how they worked; just had some vague idea about electromechanical resonance!
My best regards and thanks for the comment. (I can forward emails to ng if you wish)
Terry.
A few miles from where, in 1901, Marconi received the first Transatlantic wireless signal at St. John's Newfoundland. Now part of Canada.

OK. There's a workable schematic for an FM tuner in the RCA Receiving Tube Manuals of the late 50s/early 60s. The one I have is Edition 21 from 1961. This one is a 7-tube mono tuner using all 7-pin miniature tubes.
Although such a thing isn't impossible to locate parts for and build, its not all that practical. You can buy a similar old tuner on ebay for $10 or so and fix it up. What's the motive here, simply a homebrew project? Even still, I'd recommend buying an old tuner to get the parts that you would need to build your own. It's not an easy undertaking like building an audio amp or even a BCB radio.
I don't have a scanner, but I could take some digital shots of the diagram so that you could have a look at it. Feel free to contact me off the list at exray@coqui.net.

I'd like to tinker with DSP. Signals will be up to about 100 kHz.
What's out there that's reasonably complete and cheap?

Thanks,
Jim

A soundblaster compatible sound card?

The trick is finding the developer libraries, but if you already have the computer with sound card you already have all the hardware.
thanks, John.

Thanks for the replies. I guess I wasn't specific enough. What I was looking for was methods of detecting the mismatch. I'm trying to think how to use the two toroid approach - One senses voltage and the other current? Then apply the two signals to the two multiplier inputs? I guess with proper scaling you would get a result of zero when Rin = Rout and the phase difference is zero? I think what I'm mainly looking for is a change in phase angle between E and I, indicating the bugcatcher is off resonance. I'm open to comments and corrections!

Lou, kk5yo lbirdsong at hotmail dot com.

Look into the Analog EZLite evaluation/development boards
(http://www.analog.com/industry/dsp/tools/selection.html). They're about
$89.00 on Analog's web site. The kit comes complete and ready to program,
and you can find code examples and applications for it on the net. Using a
PC sound card would definitly be cheaper, but there's a whole additional
level of understanding that has to be conquered related to API's, libraries,
interfaces, etc.

To detect the degree of 'mismatch' with varying input drive levels was the purpose of my original post.

If you take the output of the two AD8307 log detectors which is a DC voltage you can then subtract the reflected from the forward using an OPAMP and the resulting DC output voltage is a direct reading of how good the match is to the antenna.

The higher to voltage, the better the match is.

==========

How this works is the AD8307 gives an output voltage that is the RF input level measured in dB. So, regardless of the absolute level, the relative reading between the two detectors show the forward to reverse power ratio in dB.

This ratio is a direct representation of the return loss. You can find the charts for converting it to SWR in any ARRL handbook, if you want to show it as and SWR reading. I've used the dB return loss for so many years I tend to prefer dB return loss for my display.

Anyway, this method will show the antenna match at all of the HF bands and, depending on the toroid and mechanical construction, up to 2 meters easily.

==========

It is true that if the input is varying VERY fast, the detectors could momentarily give a false reading, but that depends mainly on the capacitors used in filtering the DC output. You should be able to make it fairly accurate at any audio rate of change that you'd get for SSB transmissions.

Mechanical filters consists of a number of disks that are mechanicallly
resonant at frequencies near each other other. A filter might consist
of disks resonant at 454.0, 454.4, 454.8. 455.2, 455.6 and 456.0, for
example. These different disks are joined in an array by "bridging
wires" as Collins calls them, mechanically driven at one end of
the array by some sort of transducer, and with another transducer
at the other end of the array to convert any mechanical motion
that makes it through the array back into electrical form. Think of
it as a stagger tuned IF with a number of extremely high Q circuits.
Modern Collins filters, and the Kokusai filter have a ceramic
peizoelectric transducer. Older Collins filters have a
magnetostrictive transducer, a nickel wire in the field of a
coil, with one end bonded to the end disk of the array.

Anyone seeking mechanical filters, email me for a list of
filters for sale. jlkolb@cts.com

I think all you need to do is to detect the RF voltage level at the
antenna. The point is that the transistor is ok up to is rated maximum
output VCE breakdown voltage. If the amp is run at a lower output into
a high SWR, as long as this voltage does not get exceeded (and it is
kept cool enough), all is ok.

Simply cut back the power when the absolute voltage gets to high.

Hello all,

Does anyone have any information on modifying Motorola amplified speakers
for use with other radios. Specifically, I have a Motorola MSN6054A.
Pinouts will really help, though there is also squelch, etc and general
comments would help.

Thanks

Shuld be quite easy, if you have a schematic. Just provide 12 V and terminate your radio speaker output with 8 or 10 ohms. Usually these are only an audio power amp built into the speaker case with the speaker. don't know about that squelch thing, unless there is a control lead that removed power when the radio itself is squelched.

Up to 100 kHz? Cheap? Nothing.

The usual DSP eval boards support sample rates to 48 kHz.
Ditto sound cards. Run a sane OS and all you have to do
is read off the samples and play with them.

It can be very difficult under Windows 95/98/Me to simply "read off
samples". Under Windows NT/2000/XP it borders on impossible for the average
bear.

On the other hand, it's tricky but not impossible under Linux or VMS, not
very hard under OS/2, and pretty straightforward under DOS.

Actually, DOS probably doesn't qualify as a "sane OS", it's not really an
operating system. That's what makes it easy!

I like to tin the braid, then use a tubing cutter to trim it to length. Then I drilled out the holes to remove the plating, then soldered the tinned braid to all four holes. To reuse the connector, you clip the wire to a couple inches, heat the center conductor and pull it out, then screw the sleeve backwards to cover the center pin, use two pairs of pliers, and heat the body over a gas stove, or propane torch. Comes out clean, and ready to reuse. Guys used to laugh because I'd buy boxes of used connectors at Dayton, till they saw the results, and I never had to worry about a plug pulling off. I soldered the things with an old Weller 175 Watt iron that's still in one of my toolboxes.

6279. Looking for inductor color codes

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-14 00:51:26 UTC
From: Glenn Butzlaff <gbutzlaff@wi.rr.com>
Message-ID: <ik5y7.28447$si5.2879437@typhoon.kc.rr.com>
Source record: 49476

Can anyone point me in the direction of a web site where I can look up the color codes for molded inductors with the code in a dot
format. I have plenty info on color codes for the axial type inductors, but none of the search results yielded any info for the dot
codes. The inductors themselves have blue bodies, almost shaped like silver-mica caps. Any help would be greatly appreciated.

Glenn Butzlaff, WE9K

6280. Re: Looking for inductor color codes

Source record: 49477

The code uses the standard colors used on resistors.

Bk - Br - Rd - Or - Y - Gn - Bl - V - Gr - Wh

The first two digits are the significant numbers and the third is the
multiplier. If there is a fourth color it is the tolerance.
The value is in microhenry (uH).

Red, Red, Orange, Silver would be 22000 uH 10%

Blue, Gray, Silver, Black would be 0.68 uH 20%

This has been an industry standard for quite some time.
Hope this will be of assistance.

Played a little with cellular antennas on boats. My experience showed the importance of good coax and good connectors with external antennas. Often a simple ground plane antenna from coathanger wire is all that is needed, but as a previous responder indicated, more height is probably the best enhancement. I have a similar, poor location, which "almost" works. I put a simple, wire groundplane on the end of a 10' garden bean pole, duct taped it to the back porch railing, and it made the darned thing work pretty well. The only problem here is that I only had 10 feet of decent coax, so I still have to go out on the porch to use it. Yankee ingenouity has been summoned, so more practical solution will come before this winter's power and phone outages.

My 2 cents says it really does help to drill out the holes to a larger
size so that you can get a substantial part of your soldering tip in
there. I had some once that had slots instead of holes and they
soldered very easily. Sad part about them though, was the center pin
insulator was some cheap crap that melted easily.

I built a 16 element colinear antenna that had a published figure of 9 dB of gain and is omnidirectional. It worked VERY well. The vertical height of the antenna was in the 6 foot range.

Details are in the ARRL Antenna Handbook. Mine is dated 1974.

hello tv experts, this is a hypothetical i repeat hypothetical homebrew equipment short range tv broadcast scenario question (understand legalities, only looking for purely technical responses). I would like some help on how to estimate feasibility, theoretical or typical range (1 ft, 10ft, 100ft, 1000ft?) and signal/picture/audio quality of ntsc signal (good, acceptable, poor?) using air/wireless transmit method via off-the-shelf (radio shack) transmission equipment being a vcr channel 3/4 modulator output (~61MHz at 1v PP, 6MHz bandwidth) direct to a matched log periodic antenna. Receiver equipment being a standard ntsc television with standard oem rod antenna. Also curious of what performance increases would be seen by adding a 10db gain catv distribution type amplifier between vcr and antenna to boost signal. Actual test data or experiences appreciated. I do not have catv or television knowledge. This is a learning/mental excercise.

> What's out there that's reasonably complete and cheap?

You won't get a cheap unit that can do 200 ksamples/s.

If you don't need DC-100 kHz consider building a tunable down converter to mix down to DC-20 kHz or so, where a good quality sound card will do the job. The filtering and mixer design with the relatively small spacing and low frequencies might be tough.

If you really need 100 kHz bandwidth you'll need a real DSP development card. There are some middle range evaluation boards that would do the job.

Another solution might be to get a high speed (and optionally multiple channel) sampling card, they are even more expensive than the DSP cards and require the host CPU to do all the work, dead time will be long, RT processing is unlikely.

You can try a flash DAC to parallel port interface. I built one and could _just_ sample composite video sufficiently fast to produce a 64xN image of reasonable quality. 200 kHz of interrupts of a PC is unlikely to be very nice.

Folks---

> Actually, DOS probably doesn't qualify as a "sane OS", it's not really
> an operating system.

Any program or set of programs which allows coherent input to, output from, and processing within a computing architecture can be considered an operating system. You must be referring to a GUI style OS.

Let me remind you that *ix (Linux, HPUX, etc.), VMS, and MS-DOS/PC-DOS are all CLI (command-line interface) based OS's. As such, they provide a basic kernel (the processor interface to I/O), a shell (the user interface), and a set of programs which generate the functionality. The _ONLY_ difference between MS Windows (any flavor) and any of the CLI OS's is that MS Windows makes their primary shell a GUI rather than a CLI. In any case, all flavors of windows have CLI shells available (I once ran BASH on a WinNT box.) Some of you may remember some of the replacement shells for MS-DOS---programs that ran in lieu of COMMAND.COM.

In short: even those programs we create for microcontrollers can be considered OS's. Without an OS, a processor, microcontroller, or other computing device is simply a dummy load. ANY program which accepts input, drives input and output, and processes input and output may be termed an OS.

Hypothetically....use a few cable TV modulators. You can get the
cheaper ones under $100 brand new. Combine them thru a backwards
splitter and into your antenna. You'll be looking at nearly a volt of
RF on each channel and trust me, it will carry quite a long distance.
The little 3/4 modulators only have about +5 dbmv output...the true
modulators will have about +55 dbmv out and a somewhat narrower
signal...sometimes good enough to use on adjacent channels but I would
avoid that.
If you are restricted to the cheap 3/4 modulators, you want a whole lot
more gain than 10db. You can get amps in the >30db range. No, don't
try to cascade three 10db ones.
And please use directional antennas so that you don't hypothetically
interfere with my TV reception.

"Henry Gernhardt/Andrea Winship" <hcg_alw@earthlink.net> wrote in message news:3BC97938.DCA5A989@earthlink.net...

> You must be referring to a GUI style OS.

Hardly. I take a little broader view of an OS, however. IMO, an operating system abstracts the underlying hardware and manages those hardware resources to provide services to application programs.

The very limited services DOS provides in this respect, and the fact that it really doesn't do much to abstract the underlying hardware are exactly what makes it easy to access the hardware.

In DOS, you simply access the hardware and read the data. Laura suggested you just read the samples and play with them - in DOS, that's exactly what you do.

In all the other operating systems mentioned, you need to write a device driver of some kind. OS/2, having that DOS heritage, allows a little more direct access to the hardware, although it is still managed by the OS.

In Linux and VMS, you get less direct access to the hardware, but the device driver structure is reasonably straightforward and well documented.

In Windows, you need to jump through all sorts of hoops to write a driver, and although the documentation is basically free, MS makes it pretty hard for the average person to find and use that documentation.

Windows 95/98/Me are all basically DOS with a GUI shell. Although MS tried to hide the underlying 16 bit foundation, it's still there, and you can sometimes manage to sneak through and use DOS access to the hardware, although that isn't always possible. In NT (and 2000 and XP) MS has pretty much shut off that access and made driver writing a little more complicated.

What I was saying has nothing to do with a GUI.

> _ONLY_ difference between MS Windows (any flavor) and
> any of the CLI OS's is that MS Windows makes their
> primary shell a GUI rather than a
> In any case, all flavors of windows have CLI shells
> available

Well, I agree to a degree. One could argue that Win 9X really doesn't manage the hardware as well as it should, but if you compare the NT flavors of Windows to Linux, OS/2, VMS, MVS, RSX - any of the REAL operating systems, then that probabaly is the main difference. But DOS is basically a program loader and not much more, which is what makes it ideal for this sort of problem.

> In short: even those programs we create for
> microcontrollers can be considered OS's.

I differentiate between program loaders, program schedulers, and operating systems.

> Without an OS, a processor, microcontroller, or other
> computing device is simply a dummy load. ANY program
> which accepts

Hardly. When I program a PIC to be a keyer or counter or whatever, I have no OS, and no need for one. The application is simple enough that I need no help in managing the tiny amount of hardware that the application needs, and the application will use all of the hardware it uses in an application-specific way. My application isn't an operating system, it's an application.

Now, in the case of the PIC, I have a little collection of routines that I reuse for things like displaying to an LCD, generating PWM output, etc. One COULD, I suppose, consider these to be an operating system, but that's a real stretch.

As other people have said, 100kHz is too high for sound cards. You could use
something like the 16-bit ADI EZKIT Lite with a faster external ADC. It's
quite easy to interface stuff to the EZKIT by soldering in a header,
building your circuit on a piece of prototyping board, and connecting it
with a 50-way ribbon cable. All the signals you need are available.

> Hardly. I take a little broader view of an OS, however.

Okay. I'll accept your viewpoint. It seems our fundamental views of an OS are different. I had not considered hardware abstraction as being a requisite for classification as an OS, however I _do_ understand and accept that viewpoint.

The first PC I owned with a DOS was a KayproII. It ran CP/M. If you try really hard, you can find that heritage in MS-DOS. In earlier versions of MS- and PC-DOS, you could actually run CP/M .COM files. I remember the Kaypro quick guide I had describing the OS as the ``interface'' between human and machine---thus the reason I take the standpoint I do.

I will, however, stop harping about this, and will not try to convert any to my way of thinking. I don't want this thread to become like the ``CW Bandwith'' thread. :)

transmitter 2-810's driving 2- 813's
this is tube complement after i opened and pulled them out to check.
also has 4-866A and 2 6B4 plus a few other small tubes.
anybody have a idea what this would be worth? use BK changable coils to
change bands

On the big rig, I suspect that y ou have 5 separate driver/final amplifiers there which were probably driven by the HT-18. A single 807 is more than enough to drive a single 813, and since in the old days there were only 5 bands (80, 40, 20, 15 and 10) or even older (160, 80, 40 20 ane 10) that would account for the five output stages.

You do indeed have a treasure trove of high-power r-f components, power supplies, etc. although I suspect that a single power supply and modulator operated all five output stages.

By that definition even the BIOS would be an OS, since it abstracts
the underlying hardware. Thus, MS-DOS using BIOS services would
definitively be an OS by that definition.

However, hardly any application programs access e.g. the serial ports
through BIOS routines.

>In NT (and 2000 and XP) MS has pretty
>much shut off that access and made driver writing a little more complicated.

While this is the general principle to write a specific device driver,
but I have used industrial controller cards due to performance reasons
(several megabytes/second) in which all things that the device driver
supplied by the card vendor does, is simply to map the dual port RAM
on the card into the user mode address space and it can be accessed as
any array or structure in user mode.

A similar system for mapping individual I/O addresses directly to user
mode can be found from www.sysinternals.com site.

I haven't done this on VMS, but I guess that by installing a suitable
common area with suitable privileges, it should be possible to access
the I/O-page directly from user mode programs. In RSX-11 this was
definitively possible to map the 8 Kbyte I/O page to a user mode
program by specifying the required linker command line switch :-). Of
course privileges were required to run or install such programs.

Of course accessing hardware directly is something that you try to
avoid as long as possible in more complex operating systems. However,
using hardware dedicated to a single process in poll mode can
sometimes be handled by mapping the hardware into user mode address
space, but using interrupts or sharing the same hardware between
multiple concurrent processes will require a proper kernel mode device
driver.

Thus, in both MS-DOS and WinNT (RSX-11 etc.) hardware can be directly
accessed or it can be abstracted using OS services, so I do not see a
principal difference between these systems. Some have multitasking and
memory protection and some don't. Some have virtual memory, others
don't.

6303. FS: New power transformers for sale or trade

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-14 19:08:03 UTC
From: Terry Perdue <k8tp@home.com>
Message-ID: <noly7.8161$Zb.3512402@news1.sttln1.wa.home.com>
Source record: 49350

I have three new power transformers that would be ideal for a solid state kilowatt RF amp, high power audio amp or monster bench supply. These are real beauties, but very heavy - so you wouldn't want to pay for shipping. Pick-up only in Seattle area. Specs are as follows:

(Primaries are the same on all three - dual 100/115V (200/230V), 50/60Hz.)

Xfmr #1:

One 55V secondary, tapped at 4V, 40V, 45V and 50V. Rated at 250A peak (6% duty cycle), using a bridge and 150,000 uF cap.

Xfmr #2:

Secondary #1: 50V, tapped at 30V, 40V and 45V. Current rating not known, but substantial.
Secondary #2: 28V center-tapped at 8A continuous, 50A peak (20% duty cycle), using a bridge and 50,000 uF cap.

Xfmr #3:

One 55V secondary, tapped at 4V, 36V, 40V, 45V and 50V. Rated at 100A peak (20% duty cycle) using bridge and 50,000 uF cap.

If interested in any of these, and able to pick up, contact me, and we'll work an easy deal.

The only help I can give you is to say that the average TV should give a very good picture with 1000 uV input to the antenna terminals if there are no imperfections in the signal path. Rule of thumb in installing TV antennas is to get no less than 3000 uV, enough that the primary signal is much stronger than most multipath signals.

> definitively be an OS by that definition.

The BIOS isn't an O/S because it can't load and manage programs. Its only
"program loading" facility is to read and execute the first sector on a
disk drive.

MS-DOS using BIOS services might be an O/S *if* it abstracted ALL the
hardware.

> However, hardly any application programs access e.g. the serial ports
> through BIOS routines.

That's because the BIOS serial-port routines are so minimal. But the fact
that applications can access the serial ports directly means that MS-DOS
isn't abstracting the serial ports.

Source record: 49353

Initially it was just one button which worked intermittendly, but now
most of the buttons on my HT (IC-W21AT) don't work anymore.
Even when I exercise them a lot, they don't come back to life. Finally
I had it and opened up the HT. The question now is how do you clean
the keypad. I wiped the board and the keys. Is this enough or do I need
to replace the rubber key pad. The board looks OK and the gold plated
contacts are shiny. Any advice is appreciated.

Huh?

The Linux interface doesn't get much simpler.

Last time I did it, the way to obtain samples was to
open() /dev/dsp, use ioctl() to configure sample rate
and such, then use read() and write() to read or write
samples. Or save the hassle and pipe samples with brec
and friends. Other free OSs (e.g. Free BSD) use a similar
setup.

This is tricky?

Far and away, the best option is an industrial unit hooked to shop
vacuum source. That, like a solder sucker, will give you a vacuum
pulse that is strong enough to whisk the molten solder away without
cooling it in the joint.

After you have used a solder sucker and some solder wick, the next
step (for DIP/PTH (pin through hole) parts) is to first grab each leg
of the IC on the back side of the board with needle nose pliers and
wiggle it vigorously back and forth. Then go to the top side of the
board with a small screwdriver or awl and press each leg in toward the
body of the part right where it enters the PWB. You should feel a
small "snap" as the solder loint between the side of the legs and the
plated through hole breaks loose. Gently wiggle the part to identify
any legs that need more attention.

Hi Stephen,

Are you being forced to do it with sand-state ?
If not, I would suggest using tubes! <jaws dropping open>
If you pick up an older issue (50's or 60's) of the ARRL
handbook and look therein for a project for a 160 meter
receiver, which tunes 1.800 to 2.000 Mc and shouldn't
be too hard to move the design down to the AM broadcast
band once you understand the design.

I would think you should be able to build the rcvr using
no more than about 2 or 3 tubes (plus a power supply).
And if you use the old vintage tubes, you can make it
look REALLY cool :)

Keep 'em Glowing...

You want solid-state, or tubes ?

If tubes... Pick up an older ARRL Handbook and flip
through it.. I'm sure you'll find something there.
As for 6m... There are quite a few in the ARRL VHF
Operators Manuals.

If Solid-State... I don't have any suggestions.. :-/

6325. TS50 TX modification...How could I return to default frequencies?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-15 11:26:44 UTC
From: hackertito <hackertito@yahoo.com>
Message-ID: <3BCAC7F4.91A70C3@yahoo.com>
Source record: 49372
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hello all. I have a TS50(not TS50S) of second hand. It has full TX from 0-30 MHz, and I would like to become TX to their original values. I have surfed over the net and found some modifications, but they are all for open to full TX...How could I close the full TX and restrict it only to permitted frequencies?.
I have found on the PC board of my TS50 diodes D1,D2,D3,D4,D5. Diodes d1,d3,d4,d5 are cut on 1 of the 2 extreme(but the diode is there), but on d2 there are nothing.
What should I do? Should I solder diodes d1,d3,d4,d5 again? (and leave diodes D2 empty (as now)...I think yes but...
And also I think I should reset the CPU...

Any idea....

Best regards from Tito

6326. Re: TL071 and TL081 difference?

Hi Renfred

I can't see a reason not to use them. Jung's "IC Op-Amp Cookbook" p107,
states:
"The specifications of [the TL071 series] are similar to the TL081 series,
but feature lower noise and distortion for ac uses." ;-)

Sounds like a "go" to me!

I'll leave it up to you to ensure that the pinouts are identical...Have fun!

Best wishes
Adam

6327. "Q-Dope" rant and info request

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-15 12:30:44 UTC
From: Adam Weber <adam@home.email.ne.jp>
Message-ID: <3bcae63b$0$2303$44c9b20d@news3.asahi-net.or.jp>
Source record: 49376

Hi all

"Q-Dope"--awfully simple stuff--20% polystyrene resin, 80% Toluene, according to the MSDS. (Sounds like a very old-fashioned plastics glue to me.) It's sold in many places in the USA, but I can't find anyone who will ship it overseas, even in 60ml/2oz bottles. [$^%%$%$## postal regulations!]

There's a locally-made product which is supposed to be a 'coil varnish' for only ¥150, but I don't think I'll live long enough to ever see the stuff completely dry! It smells just like hot bakelite as it's "curing"... (a nice, nostalgic smell, to be sure!) but I think I've waited up to 9 days now, and the stuff is still tacky and looks like being a great dust collector. [I bought 2 bottles, with slightly different labels, indicating an age difference...both give the same results...]

Does anyone know a substitute for "Q-Dope"? Can I get by with plastic model cement? I've found one that contains polystyrene resin, but has a whole lot of other gunk in it as well, including acetone. Anyone tried nail polish? I've also come across an American product here called "Crystal Cote" that is supposed to be some form of hobby varnish (tole painting, perhaps?) The label doesn't state the contents, but there is a warning to the effect that it is a resin in solvents, including toluene.

I've got a friendly local pharmacist looking for the makings, but I'm a tad doubtful about getting the toluene. Does anyone know if Xylene will do the trick?

I'm happy to do a few small experiments, but don't want to kill myself. I don't know enough organic chemistry to understand all the reactions of plastics. Is it worth trying to dissolve polystyrene foam (or even polystyrene capacitors?) in organic solvents? Do I NEED to use Q-Dope? [OK, maybe I'm a bit 'anal' that way--but I like to "follow the directions" implicitly...]

Sorry for all the questions, but I've GOTTA get some of these toroidal transformers made soon!

Cheers
Adam

Use the Minicircuits VCO, a crystal Osc and a mixer. Then you can use
it where yo want it. Add more crystals, get more bands.

I personally feel this explanation to be misleading. Everything revolves around the sneaky use of the word 'percentage'.... which indirectly suggests that people are probably adjusting the rise/fall times so that they are a constant percentage of the mark period when they change keying speeds. I sure don't do this and I still haven't found any control on my transmitter for routinely making such adjustments.

I bet if you get 100 entry-level hams to read this sentence and then explain what they just read - then you would find that the meaning of 'percentage' did not sink in for many readers and they were left with the impression you were trying to say that the effective spectrum range is determined by the keying speed itself (not the rise/fall times).

From the ARRL License Manual 1976:
CW Bandwidth = wpm X 4 (e.g., 40 WPM = 160 Hz)
"With proper shaping, the necessary keying bandwidth is equal to 4
times the speed in words per minute for International Morse Code;
e.g. at 25 words per minute, the bandwidth is approximately 100 cycles."

Hi folks

I've begun the obvious experiment. The Xylene "works" to some degree. The polystyrene packing beads dissolved very nicely. The resulting gunk also 'skins over' pretty fast and resembles white woodworking glue (PVA) as it dries. I guess that whatever is left over after the Xylene evaporates is polystyrene...unless there is also a chemical reaction that I don't know anything about. I managed to dissolve quite a boxful [maybe 40g or thereabouts(?)] of foam in about 80ml of Xylene.

I think acetone and lacquer thinner would work just as well. Mineral spirits can certainly dissolve polystyrene, as well...DAMHIKT!

I found a reference to an article in "QRP Quarterly" suggesting that "Shoe Goo" can be used on toroids. It was only an index entry, tho, and I couldn't find the article anywhere. It would have made an interesting read...

Thanks for the input

Adam

> polystyrene...unless there is also a chemical reaction that I don't
> know anything about.

Xylene is actually a relatively inert solvent. It is related to toluene in that it is an aromatic compound, toluene being methylbenzene, and xylene being dimethylbenzene. There are actually three flavors of xylene: 1,2-dimethylbenzene (o-xylene), 1,3-dimethylbenzene (m-xylene), and 1,4-dimethylbenzene (p-xylene). The distinction is the relative positions of the methyl (CH_3) groups on the benzene (C_6H_6) ring structure.

Toluene and xylene are often used in college organic labs as simple solvents. The reason is that it is very difficult to break apart the aromatic structure of a benzene ring, and it is also rather difficult to remove or alter the methyl group(s). As such, I believe that what you have remaining, after the xylene evaporates, is polystyrene.

NOTE TO CHEMISTS LISTENING: I have not had any organic chemistry in quite some time. If I have made any errors (such as the ortho-, meta-, and para- positions, or reactivity issues), feel free to and PLEASE correct me. I do not want disinformation spread as gospel.

Thank you,

Parts for Sale as of 10/15/2001
==========
NEW .1 uF Poly/Film caps - 10% 250v, new stock, paper tape, nice long leads.
These are not NPO and are made by S&M Components

50 for $3.00 100 for $5.00

22uF 35v electrolytics - $1.00 and 2 stamps for 100 These caps are on paper
tape, NOS (New, but old stock) made by Richey. I have thousands. Oh boy.

I have NEW BNC chassis connectors for (includes nut and lock washer)
==========
25 for $12.40
50 for $21.00
100 for $36.00

Voltage Regulators
==========
LM7805C voltage regulators. TO220 case. 5 for $4.00
L7806CV voltage regulators. TO220 case. 5 for $4.00
LM7808CT voltage regulators. TO220 case. 5 for $4.00
LM7812T voltage regulators. TO220 case. 5 for $4.00

Get 5 of each for $15.50

Transistors
==========
2N2222's in METAL TO18 case - 25 for $7.50 NEW PARTS
2N2222's plastic TO92 case - 50 for $4.00 NEW PARTS
2N3906's plastic TO92 case - 50 for $3.50 NEW PARTS

Crystals
==========
8.192 Mhz crystals HC49 25 cents each, and a 1st class stamp. (I have 100)
Use them for filters? These are NEW.

3.579545 Mhz Crystals for 80m - These are pulls, $2.00 each

POTS
==========
10K 1 Turn Panel mount pots. These are pulls. No knobs, just shafts. Most
are Allen Bradley. Pot is about as big as a quarter. With nut. 5 for $4.00

Diodes
==========
1N4148 - You always need these. 75 for $2.00 These are NEW.

Speakers
========
Little 3 inch PC speakers, 8 Ohm. $1.50 includes shipping in a padded envelope.
10 for $8.00 - They work great for little external speakers on QRP rigs. Just add a audio amp you make from 2N3906's and you can run your neighbors out of their house.

Inductors
=========
Any order over $10 gets 10 genuine 100 uH, made in Russia, shipped from Lithuania, inductors. I do not guarantee these to work, I have nothing to test/check them with. Put them in your junk box.

Let me know if you're interested. All prices are post paid to the USA, unless otherwise noted. I will ship to non USA addresses but we need to discuss the shipping charges first.

Thanks - My address on QRZ is good.

Hi Henry

Thanks for the very clear and succinct technical rap--it sounds like what I read in textbooks a l-o-o-o-ng time ago.
I recall that Xylene, especially, is used a lot in microscopy for the reasons you stated.
I'm guessing, now, but I expect that Toluene has a lower 'flash-point' and might vaporize more quickly...one thick test sample in Xylene hasn't hardened yet--it's been sitting over-night, too. "Q-Dope", I understand, is very quick-drying.

I still hope my pharmacist can track down the "correct" stuff.

Cheers
Adam

Hi all

Acetone and Xylene seem to be the most "popular" recommendations for the solvent, with lacquer thinner another possibility.

Concrete sealant, plastics glue, nail polish, possibly "Shoe Goo" all sound like near-enough substitutes.

For some reason, I recalled a product that almost no American home was without in the 50's--wasn't there a product called "Stanley Glue"? The color, the packaging, even the brush fitted into the top resembles Q-Dope. I wonder...Seems it was used for just about everything, the way CA superglue is used today.

Thanks for any and all input

Cheers
Adam

How closely related is model car cement to Q-dope? Thats what I used to
use many years ago but they might have changed the formula to make it
less "sniffable". The last I bought was in a dropper-type bottle and
very thin. BTW it now says Xylene, not toluene on the label and doesn't
work as well for models.
Another possibility is the UHU in a tube. At least it resembles
Q-dope. I have no idea of its properties.

Rob, I suggest that you find a factory built VHF/UHF transceiver ,open it up and take a "looksee". building anything useful is out of the question..However, you can build some of the accessories that go with ham radio and have fun there.. good luck Harold W4PQW

Hi Bill

"Tamiya" brand, available here, contains 11% polystyrene and the major solvent is acetone, with some cyclo[?]-Hexane and an as-yet-unidentified 'butyl-' compound. I agree that it's thinner than in 'the old days'...should work, though, as long as it can hold the windings and coat the transformer with a skin of polystyrene.

Funny how life works...The pharmacist just called and said he can get the Toluene--very cheap, too--but no luck on the resin! That shouldn't present too many problems, though. I think I know a craft shop that might stock it...fingers crossed!

Cheers
Adam

6356. Re: OT : CW Bandwidth

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-16 08:57:00 UTC
From: Graeme Zimmer <gzimmer@optushome.com.au>
Message-ID: <wDSy7.5773$bE1.26135@news1.rdc1.nsw.optushome.com.au>
Source record: 49402

Facinating stuff.... . Here are the facts as I see them....

(1) If a CW TX had no Keying Filter, the key-click sidebands would extend to infinity.

(2) With no filtering, varying the keying speed would not affect the ultimate BW, but would dramatically affect the distribution of the energy peaks (and nulls) in the sidebands.

(3) In a real world CW TX, the ultimate BW is primarily decided by the keying filter.

(4) Within the BW allowed by the keying filter, the keying speed will dramatically alter the sideband shape, but it will not affect the ultimate bandwidth.

(5) For minimum bandwidth keying, the envelope shape should be optimised for each different keying speed.

(6) For minimum bandwidth, a Raised Cosine (or similar) shape is required. This shape can really only be achieved with a DSP filter (e.g. FIR).

(7) The usual Keying filter is a simple fixed RC network. Such a network cannot give the ideal keying shape.

What is my bottom line?

The ultimate CW bandwidth is not decided by the keying speed, but by the time constants in the keying filter.

The common statement that "Keying speed decides the BW" is simply wrong, as it assumes that the key filter time-constants are changed for each keying speed.

If you want to do this in real-time under Windows, it's tricky. For learning purposes you could capture some audio input in a WAV file, and then write DSP code in C to manipulate the file, then play it back through the sound card. The SOX (Sound Exchange) code would be worth looking at. You should be able to find it with a web search.

True.

> (2) With no filtering, varying the keying speed would not affect the
> ultimate BW, but would dramatically affect the distribution of the energy
> peaks (and nulls) in the sidebands.

True, if by "ultimate bandwidth" you mean the range of frequencies which contain any power from the signal. With or without
filtering, keyclicks extend to infinity. They are simply at a lower level with a filter.

> (3) In a real world CW TX, the ultimate BW is primarily decided by the
> keying filter.

False. You're mixing terms here. "Ultimate BW" is by nature theoretical, and cannot be applied to a real world example. If you
mean bandwidth in the common sense, i.e. the frequency range which contains x% of the signal's power (choose any x), then
bandwidth is primarily decided by the keying speed.

> (4) Within the BW allowed by the keying filter, the keying speed will
> dramatically alter the sideband shape, but it will not affect the ultimate
> bandwidth.

True, only because the "BW allowed by the keying filter" and "ultimate bandwidth" are both infinite, and therefore equal. If you
mean bandwidth in the common sense, i.e. the frequency range which contains x% of the signal's power (choose any x), then
bandwidth is primarily decided by the keying speed.

> (5) For minimum bandwidth keying, the envelope shape should be optimised for
> each different keying speed.

True, although producing minimum bandwidth keying is undesirable, as such keying would also make for very difficult copy.
That's why "harder" keying is needed for worse conditions.

> (6) For minimum bandwidth, a Raised Cosine (or similar) shape is required.
> This shape can really only be achieved with a DSP filter (e.g. FIR).

Unproven.

> (7) The usual Keying filter is a simple fixed RC network. Such a network
> cannot give the ideal keying shape.

True.

> The ultimate CW bandwidth is not decided by the keying speed, but by the
> time constants in the keying filter.

True, again, only because "ultimate bandwidth" is infinite. If you mean bandwidth in the common sense, i.e. the frequency range
which contains x% of the signal's power (choose any x), then bandwidth is primarily decided by the keying speed.

> The common statement that "Keying speed decides the BW" is simply wrong, as
> it assumes that the key filter time-constants are changed for each keying
> speed.

False. For any given keying shape, a string of dits will consume greater bandwidth than a string of dahs. Likewise, higher speed
Morse code consumes greater bandwidth. Keying shape has very little effect on the bandwidth (common definition, not the
meaningless "ultimate bandwidth" one.)

... actually, not long ago, QST had a series of articles about
building a QRP all mode VHF transceiver. While it was pretty much a
kit project, there was quite a bit of hands-on involved... Might be
worth a look...

If you're an ARRL member, go to the website and search for Homebrew. I think you have to be a member to use the search features of TIS...but I could be wrong. The ARRL is giving away an awful lot these days.

www.arrl.org

The Technical Article Section has several VHF and UHF rigs you can build.

In the US, looking at the lable on my can of lacquer thinner in the
garage it seems that the biggest ingredient is toluol which I assume
is touluene. So check the labels of the stuff in your local
paint/hardware stores. I suspect you don't need help from the
chemist (other than real chemists for detailed questions). Melting
the styrofoam pellets in lacquer thinner or some finer solvent
should work, I think.

Hi All;
I have a bunch of Circuit Board kits which have already been assembled by someone.
They are really nicely made on Copper boards with nice bright soldering.
They are mostly for 12vdc operation and all come with a hand drawn schematic.
All are very similiar to the pictures, some may vary as far as component colors, board sizes & component placing.
All components appear NEW!
I am not a designer or a technician so please check the pictures before E-mailing me or asking questions because I may not be able to answer them completely and I do not know the Power output of any of these devices or even thier uses. The Prices are with US Priority Mail included.
These items are mostly for Experimenters & hobbiests.
If you need more then one(1) item, please e-mail for Better Total cost!
Please repond by using the Item number that is written on each circuit, this will make it easier for all as they are many which look alike & are confusing ;-)

This coming Sunday.... The seasons last....

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday October 21st 2001
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all

sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Hi homebrewers,

I want to arrange qsk/full break- in with a 100 W push pull solid state PA driven by a qrp xcvr.

Currently, the PA has a relay (slow) circuit, which I wish to replace with a solid state, fast cirucit.

The qrp xcvr can provide a voltage shift from +8 to 0 V a few milliseconds ahead of any RF power from it.

Anyone out there who could help me?

Thanks, 73's de Per / SM0WRA

I made some coil dope by disolving styrofoam pellets and small chunks
into a couple ounces of acetone. I haven't had occasion to use it yet
except for testing to see how it appears to adhere but I believe it will
work OK.
I sealed it by using aluminum foil under the lid of the small glass jar
(as done on the acetone container) otherwise it will evaporate and dry
out.

(list deleted)

My take would be that for sale ads are fine, IF the items being sold are of specific interest to homebrewers. The parts that were offered in this post were indeed targeted at ham builders, including popular items such as bypass capacitors and BNC connectors; therefore, the post was appropriate.

Ads for complete radios (except possibly for one-of-a-kind homebuilt rigs) and other things that are already well-served by the other amateur radio newsgroups don't belong here, in my opinion.

Frankly Rob... I disagree with those telling you that homebrewing anything useful is out of the question. I suggest (as I have to others that wanted to learn) that you obtain an issue of the ARRL Radio Amateurs Handbook. For transistorized stuff you'd ptobably want to find something newer than a 1960's or 70's edition, unless you want to work with tubes (my personal preference).

There are several projects JUST in the ARRL HB that are for Sand-State receivers/transmitters (and tranceivers) that put out a few watts (mw to 5w), up to high pwr transmitters/amps for 144/220/432 etc that have outputs in the 100-500 watt or better range (tubes).

I have the 3rd edition of "The Radio Amateur's V.H.F. Manual" by ARRL that has projects for low power (1-5 watts) VHF and UHF transceivers, transmitting converters (Transverters) up to 1296 MHz, 100-1000 watt amps, plus all yoiu need to know to build an effective antenna array.

While it's true, this is all ANALOG tuned gear, if one get's into the later years of the handbooks (80's, 90's, and 2K) I'm sure you'll find some PLL synthesized and microprocessor digital display projects.

I seem to recall seeing almost a complete chapter in my 1991 ARRL HB for building a computer controlled Shortwave Receiver, and who knows, perhaps in the newer issues there would be the same type project for building a VHF/UHF computer controlled 'exciter', that would let you use not only voice (phone) - but also the digital modes directly with no need for any external units (save maybe an RF amp ;).

Just some thoughts... I'm sold on the ARRL handbooks.
When I was a youngster in Jr.High and HS that was my favorite read in the library...

I still don't have a life <grin>.

Well now i have finaly built an oscilator to use with my worldband radio... Works great to recieve ssb and cw but only have about 2k of bw due to crystal and not ceramic resonator.. My next project while i am waiting on mouser to mail it to a friend in the states is to start some pic work.... My first question is can someone direct me to plans for a programer for pic nothing specific yet. I don't know too much about them.. I am however fairly fluent at c and have had experience with asembly code...(Old C64 Programer...)

****
Tesla Radioclub invites you to DX-Contestvention East

You asked for it! Dayton too much? Visalia too far?

Here it is, chance to rub elbows with fellow hams and tell the lies long into the night, on Nov. 9 - 11, gathering of DXers and Contesters (big guns and little pistols) on the East Coast, conveniently located near NY/NJ/PA tri-state area at 140 acre Verkhovyna Mountainview Resort in Glen Spey, NY (near Port Jervis, NY and Matamoras, PA). See www.Verkhovyna.com for directions and maps.

Friday, Nov. 9, 2001

Pizza - Beer party, funny videos and slide shows, giant hospitality suite, bar open,
demo of new gadgets

Saturday, Nov. 10

Breakfast,
Morning forums - Antennas, propagation
Lunch break, demos, flea market
Afternoon forums - operating aids and techniques, computer assist, equipment mods
Awards dinner
Giant hospitality suite, videos, slide shows, bar open

Sunday, Nov. 11

Breakfast
DXpeditions, VHF forum, digital modes, emergency communications

Call for papers on above or other subjects, please send proposals to K3BU@aol.com before Oct 31.

Hotel/motel accommodations are available. Clubs can reserve rooms for about 10-20 people, Boy Scout style. Camping and RV parking is available.
Clubs are encouraged to reserve rooms early.

Mark your calendar and watch for announcements on www.verkhovyna.com and click on Events.

Great chance for big guns and little pistols to get together in the magnificent mountain setting, learn, have fun and meet all those people behind their callsigns.

For more info and arrangements please contact

6380. Good day at the Goodwill

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-10-16 21:45:08 UTC
From: Rick Haub <rhaub@midwestmicro-tek.com>
Message-ID: <3BCCAA64.F80B0563@midwestmicro-tek.com>
Source record: 49426

I stopped at the Goodwill this morning to drop off a bunch of old shoes and such. The drop box is around the back of the store and while I I was dropping off my old stuff I noticed that the dumpster a few yards away from the drop box had 4 old plastic AM BCB radios sitting on top of it. A Goodwill worker happed to be hauling out another box of junk at that time so I ask her if I could just have the radios. She said that they had test bad so I could have them. Total score of any worth

2) 50C5s
2) 12BE6 mixers
2)12BA6 pentodes
2) 12AV6 ?
4) 365 pF variable caps, one with built in vernier control
4) 455KHz IF transformers
5) speakers
4) audio transformers
2) good loopsticks
4) audio pots with built in on/off switches
2) power NPN transistors with heat sinks both can be used for RF PA finals
misc. odds and ends

I'm building a crystal radio with one of the loop sticks and one of the variable caps tonight with my nephew. And this weekend I'm going to build a regenerative radio using one of the pentodes and one of the 50C5's for an amp, I think. (see my next post on this).

Source record: 49428

I got a couple of 50C5 tubes the other day and I was wondering about using them with a standard 12 volt or 6 volt supply. Oviously I will not get the same amount of power but just what can I expect? Or will they even work at all?

I also picked up a couple of 12AV6s. What are these? They seem to be two diodes and a triode all in one envelope.

The 50C5s won't work at all on 12v; the 12AV6 is a diode detector/avc detector and 1st audio, usually resistance/capacitor coupled to the 50C5 or similar. VE7AFN/M.

Consider making a simple drying oven from a cardboard box, some alum
foil, and a small light bulb. Just be careful to keep the temp down to
something that won't bother any of your other components.

A day at 80C should do wonders and still not hurt anything.

I never go anywhere without some small tools, in case I see some
piece of electronic equipment in the garbage. Sometimes it's worth
bringing the whole thing home, but other times I can't be bothered,
and it's nice to be able to extract the key parts.

When people ask where they can get "365 pf variable capacitors",
I tell them to look in the garbage, and at the very most, buy
an old radio at the Salvation Army or garage sale for the capacitor.
Such junk radios can be had for less than ordering away for a "new"
capacitor.

I haven't seen tube stuff in years. I do see a lot of solid state
"stereos", and along with the tuner section (those ceramic filters
may be useful for something, though a bit wider than would be

nice), I make a point of extracting the power transformer.

Along with the traditional radios, I now see a fair number of microwave ovens (I've yet to bother with those), and of course computer equipment. Dot matrix printers seem to be quite common at this point, and they usually have lots of plastic encased power transistors.

I've even seen a couple of big oscilliscopes in the garbage in the past few years, but since I already have a working one (and it's even heavier than those I saw), I didn't bother dragging them home.

Go to the Microchip website (www.microchip.com) and download the manual
for the mid range CPUs.

PICs are a bit primitive and quirky, at least compared to the 6800,
6809, and 68000 CPUs I was used to. Code space and data space are
completely separate, so I had to rethink how I did simple operations
like table lookup. Also, the stack is only eight levels deep, so if you
use interrupts, you have to watch out how deep you get in subroutine
calls. The code needs to be pretty flat.

The instruction set is very simple (primitive). However, if you require
something complex like a multiply or divide, their website has a large
library of math subroutines available free for the downloading.

Not all PICs are a like. The really simple ones like the 0.5K, 8 pin
12C508a does interrupts differently than the mid range CPUs, and only
has two levels of stack.

That all said, they are cheap, very available to hobbyists, and
tremendously useful, which cannot be said for other more normal single
chip processor lines.

If you have written in assembly before, you will do fine.

Hi All;
I have a bunch of Circuit Board kits which have already been assembled by someone.
They are really nicely made on Copper boards with nice bright soldering.
They are mostly for 12vdc operation and all come with a hand drawn schematic.
All are very similiar to the pictures, some may vary as far as component colors, board sizes & component placing.
All components appear NEW!
I am not a designer or a technician so please check the pictures before E-mailing me or asking questions because I may not be able to answer them completely and I do not know the Power output of any of these devices or even thier uses. The Prices are with US Priority Mail included.
These items are mostly for Experimenters & hobbiests.
If you need more then one(1) item, please e-mail for Better Total cost!
Please repond by using the Item number that is written on each circuit, this will make it easier for all as they are many which look alike & are confusing ;-)

Looking for Eimac 290A detailed tube data

The tube is marked '290A' and sits on a SK-291A socket.
It's probably a 5kW HF and up ceramic tube.
I would guess it may compare to nCX5000 equivalent or (?).

/Chris

Amazing how much of it still works, too.

Silly thing to throw out. My Citizen GSX-230 Color still works fine,
and is the backup for our inkjet.

I picked up five old scopes a few years back for $5 each. Four of
them were up and running after replacing the power supply fuses.
Unfortunately, I gave away three good ones and the bad one, then the
one I kept started flaking out.

You guys would drool over what is in our company dumpster...

I hate to, but I've had to throw out brand new electronics.

And I still have a FULL garage, attic, basement...
The war department (Wife) has approved my renting a storage unit,
so I can restore some sense of order in my home...

Not quite. It is toluene alcohol. I'm not sure what the chemical composition of toluol is, however it is either some flavor of methylbenzanol, or hydroxymethylbenzene (only one flavor).

> So check the labels of the stuff in your local paint/hardware stores.

Always a good idea even if you aren't looking for a specific solvent. Many of these things have a maximum permissible exposure limit. One should _ALWAYS_ obtain, retain, and study the MSDS for any organic solvent or chemical, and preferably for any household chemical (yes, that includes standard household bleach, which is either 5% or 6% NaCLO by volume---Clorox also had (has?) a product which is 5% NaOH!). AT THE BARE MINIMUM you need to be familiar with toxicity, corrosiveness, environmental hazard, and flamability levels of chemicals used.
